In making a selection, the fact that the average owner is prone to neglect the battery should not be lost sight of. This is an unfortunate condition, but nevertheless one that must be met, and the car designer must choose a battery that will most satisfactorily withstand abusive service. He should select a battery that has the reserve capacity to start the engine in cold weather when conditions are most unfavorable. He should locate his battery on the chassis where it will be convenient for the driver to maintain it.

The car manufacturer does not warrant the performance of such parts and equipment as he buys from other companies, and the battery is included in this class. However, when a car is sold, there is some moral obligation that it will give satisfactory service in the hands of the owner. Despite the fact that the car manufacturer is not responsible for the performance of the battery, he is very much interested in it. The owner expects service from his car, and if he doesn't get it because of an unsatisfactory battery, he is disappointed. The prestige of the car suffers in his mind, and in the minds of the people with whom he comes in contact.

Satisfied owners are becoming an increasingly important factor in automobile merchandising, and in this competitive market the dealer needs all the assistance that he can get from this source. A battery that is not selected purely on the performance basis, jeopardizes the prestige of the car. Free service on the battery under the warranty is performed by the battery service station, and consequently the dealer is not under any direct expense if the battery gives trouble. But an unsatisfactory battery increases the selling expense because the dealer does not have all the assistance that satisfied owners can give him.

Capacity is perhaps the most important factor in battery performance. The battery must be able to start the engine in cold weather when the oil is congealed, when the fuel vaporizes poorly, and when the normal capacity of the battery is very materially reduced. These are the most difficult conditions under which the battery must operate. They are the conditions which the engineer must have in mind.

Increased capacity naturally means increased cost. Capacity can only be secured by increasing the size of the battery. But the difference is hardly worthy of a second thought when considered in comparison with the resultant increase in owner satisfaction. On a large production job, a small saving on each battery amounts to a considerable sum, but it is an economy that is dearly paid for.

A somewhat parallel case is found in tire equipment. Some years ago fabric tires were standard on all makes of cars. Since the development of the cord tire there has been a gradual change until now most makes are equipped with this type of tire. The cord tire is more expensive, but it gives better service. Car manufacturers have found that this addition to the first cost has increased the salability of their products. There is no reason to believe that a similar investment in an oversize battery would not produce results that would justify themselves.

Careless Owners

The careless owner is another factor that the engineer must consider in the selection of the battery. An analysis may show that a certain size of battery will meet the needs of the car assuming that the driver takes care of the battery and uses it judiciously. But the battery that is dependable under favorable conditions such as these, may be very unsatisfactory in the hands of a driver who does not bother to maintain it. A battery with reserve capacity is needed to keep this man's car on the road.

A statement that car manufacturers have economized on the first cost of batteries would be impossible to prove, nevertheless there are battery service men who believe that, in many cases where battery trouble is experienced, it is the result of the car manufacturer's economizing on this important piece of equipment. The belief is also current that battery trouble is often traceable to the fact that the battery specified for the car is too small.

Some years ago O. W. A. Oetting of the Willard Storage Battery Co., presented a paper before the Society of Automotive Engineers, in which he gave a table of recommended battery capacities as related to piston displacement. The writer applied this criterion to about forty popular makes of car, and found that about 25 per cent of them are equipped with batteries that are too small. There are no records to show, however, that the makes of car that do not measure up to this criterion experience more battery trouble than those which meet its requirements.

Price should not enter into the selection of a battery. If a car must be built to sell at a certain price, the battery is the wrong place to economize. It is one of the weak links on which the chain of owner satisfaction is dependent, and it is well worth while to bolster up its strength in every possible way.

Plate Thickness

The effect that the thickness of the plate has on the life and service of a battery also merits serious consideration. The capacity of a cell depends on its positive plate area and, in the automobile battery, this area has been made large in order to get sufficient current for starting. The weight and bulk of the battery must be kept down, however, and this has caused the use of a plate that is comparatively thin. The thin plate has two disadvantages: First, it is mechanically weak in the direction of the stresses produced by buckling. Second, due to the gradual disintegration of the active material in the positive plate, the thick plate has a longer life than the thin plate, inasmuch as it has more active material to shed, than a thinner plate.

Considerations of weight, bulk and price have doubtless influenced the selection of the thin plate battery. But it seems that it might be worth while to disregard these objections because of the important advantages of the thicker plate. The advisability of this procedure is indicated by the unusually successful results that have been obtained with thick plate batteries in passenger car service. It is not uncommon to find batteries of this type that have seen four and five years' service without being opened.

The thin plate will give dependable service provided it receives proper care and is used judiciously. But it lacks the ruggedness of the heavier plate, and consequently will not stand up as well under abuse. For this reason the thick plate is preferable, as the average driver does not show any particular interest in the battery until it refuses to crank the engine, or fails to supply current for the ignition and lights.

The rate at which charging current is supplied to the battery by the generator has a determining effect on battery performance. The driver who makes long daylight runs at touring speeds makes a very small demand on the battery, while a doctor who uses his car for making calls in a city puts a very heavy load on the battery because of the number of starts and the shortness of the intervening runs. A charging rate that would keep the doctor's battery in good shape would overheat the other man's battery, and a charging rate that would answer for the first man would starve the doctor's battery.

The charging rate is ordinarily set by the manufacturer of the electrical equipment to meet the requirements of the average driver as nearly as they can be judged. Some electrical manufacturers seal this adjustment, and their warranty is invalidated if the adjustment is changed without their authorization. It is not generally believed that the typical owner has sufficient knowledge and experience to make this adjustment.

Assuming the correctness of this viewpoint, it appears that it would be well worth while for dealers to watch all cars they sell for some weeks after delivery, in an effort to determine whether the current adjustment on the generator is correctly made for the needs of the individual driver. This is a problem for the dealer to handle, but the manufacturer might well exert his influence to secure a more general adoption of this policy.

However, there are some practical men who do not believe that the adjustment of the charging rate is beyond the ability of the owner. They believe that this adjustment should be made accessible so that the owner can change it conveniently. One battery man with whom the writer talked goes so far as to say that the adjustment should be brought up to the dash. He argues that this adjustment is very nearly as important to the operation of the car as the adjustment of the carbureter.

Owner Education Difficult

It seems to be an impossible job to educate the owner into taking care of his battery. He will keep oil in the crankcase, and perhaps give the various grease cups that are distributed around the car a little attention now and then. But the battery is hidden from his view, and may not give any warning of its condition until expensive repairs are necessary. Its chances of being maintained are very poor.

The battery manufacturers are attempting to combat this negligence by giving periodical free inspections, and they are meeting with some success. The automobile manufacturer can help in this work by making it easy for the owner to maintain the battery by putting it in an accessible position. The battery has been put in almost every part of the chassis, often without giving the convenience of the owner and the service station the slightest thought. From the standpoint of accessibility the most desirable position is in a box on the running-board, but present styles demand clean running-boards. This is where the battery was first placed, and it would be a good thing for battery performance if it were returned to this position.

In placing the battery in the chassis the engineer should consider both the owner and the service station. The owner adds distilled water and makes hydrometer tests. At least he should do this, and the chances of his doing so are immeasurably enhanced if he can do the job without removing a large number of parts and going through a lot of gymnastics. The service station has to remove the battery, and it should be placed so that it can be lifted out with a straight pull. By making the battery accessible and easily removable, the charges the owner must pay for battery service will be reduced. The battery should not be placed near the exhaust pipe, since it gets rather warm in summer and any outside heat only makes conditions worse.

There is a need for an instrument that will show both water level and state of charge in all cells by means of an indicator on the dash. Various devices have been developed which partially fulfill this need, and some of them have considerable merit. But none of them indicate the battery condition completely. One of them indicates conditions in one cell, another warns of excessive temperatures by means of a thermostat clamped on the connector, and a third provides for measuring the voltage at a fixed discharge rate. An instrument that would indicate battery conditions completely should have a wide sale and should lead to improved battery performance.

Car manufacturers have done much to simplify the problem of battery service within the last few years by the adoption of standardized types of batteries. There is still room for improvement in this respect, but conditions are much better than they were some years ago.

The battery must be proportioned to the size of the engine. This precludes the possibility of having one battery that will be standard for all cars. But it is possible for the automobile engineer to arrange the chassis so that a standardized type in the capacity required can be used. There is no good reason why two cars, having 6-volt electrical systems and using 100-ampere-hour batteries, should not use the same type of battery. The reason this is not always possible is because the shapes of the battery compartments are not

the same and the leads are not brought out in the same manner.

The use of standardized types in the different capacities has two important advantages. First, the cost of the battery is reduced, due to the economies of large production, and, second, the problem of supplying service is simplified.

The battery service station must be prepared to supply a new battery for any car, and also to supply a rental battery to the owner whose battery is undergoing repairs. If the car manufacturer arranges his chassis so that a special battery is required for it, then the dealer must stock new and rental batteries in order to render service on this car. On the other hand, if the car is designed for a battery that can be used in several other makes of cars, the dealer can economize on his stock.

In 1920 cars this difficulty is less pronounced than in previous years. In fact, each year has seen a reduction in the number of battery types required for the better known makes of car. A survey of forty popular American cars shows that eleven different types of batteries are required for these automobiles. The word type covers the size of plate, number of plates per cell, number of cells and the arrangement of the cells, but does not include the form of terminals required. Four plate sizes are used in these eleven batteries.

Standardized Terminals

Standardized terminals are not as important as standardized types. It is a simple matter for the service station to provide terminals that will fit the cables on the car. However, standardization of terminal forms has not progressed as far as the standardization of battery types. Seventeen terminal arrangements are required for the forty makes of cars considered.

One battery out of the eleven fits ten of the forty cars. Five of these cars have the same terminal arrangement, but four different terminal arrangements are required to service the other five in this group. The most favored terminal construction is the bare taper post to which the cables are clamped. It provides the simplest arrangement for the service station and appears on more cars than any other form of terminal. It would doubtless be an improvement if all manufacturers adopted this type of terminal, as the construction gives very satisfactory service.

The present method of handling standard equipment batteries is not entirely satisfactory. If the battery is shipped wet, its life commences just as soon as the battery manufacturer puts electrolyte into it. From there it goes to the car manufacturer, who installs it in the car. The next step is the shipment of the car to the dealer, who, in turn, delivers it to the customer. If the demand is ahead of production, a comparatively short time elapses before the battery is in actual use.

Wet or Dry?

The longer the period that elapses between the time the battery is made ready for service and the time it actually goes into service the shorter will be its useful life. Furthermore, if the battery is not given an occasional boosting charge during the period before delivery, there is a strong possibility that its plates will be damaged. This is a real objection at this time, because there are instances where batteries have been in the hands of the car manufacturer and dealer for over a year before delivery.

In the case of a battery that is shipped dry, no loss of life or plate deterioration takes place. However, this practice is also open to objection. When a dealer goes to the freight station to get a car he must take a battery with him to replace the dry-shipped battery that comes with the car in order to get current for the ignition and starter. The battery shipped with car must then be prepared for service. In some places this matter is handled in the following manner: The car dealer takes the dry battery to the battery service station, who gives him a battery that is ready for service in exchange, charging the dealer a small fee for the work involved.

Shipping the battery wet is open to the objection that the customer may get a battery which has used up much of its useful life. Shipping the battery dry is open to the objection of the trouble and expense of putting a serviceable battery in the car. It has been suggested that both of these objections could be obviated if the car were shipped to the dealer without a battery. When the dealer sells the car he could draw on the local battery dealer handling the battery which is specified as standard equipment for a battery to fit the car. In this way every car purchaser would get a new battery, and the dealer would not have the expense of switching batteries. This method might introduce some complications, but it is thought that a satisfactory method of handling standard equipment batteries in this manner could be worked out. In the case of batteries shipped wet it would be a decided improvement over the present method.

On the whole, the battery gives reasonably satisfactory service in view of what is expected of it and the care it receives. The most important factor affecting its life and dependability is the care and use given it by the driver of the car in which it is installed. A great deal can be done to improve battery performance by the education of the owner on these points.

Tolerance Systems for Cylindrical Fits

(*Continued from page* 1280)

shaft should be of such a size as to give the quality of fit desired, all tolerance on the shaft being minus. This rule should be strictly adhered to for interchangeable manufacture. In case selective assembly is to be employed then the tolerance on the shaft may properly be plus.

"A temperature of 68 deg. F. (20° C.) was adopted by the Bureau of Standards and by the War Department as the standard temperature for all munition gages in 1917, and was used in all gage work during the war. This temperature has also been selected by the National Screw Thread Commission as the temperature at which all gages and gaged products should be standard, and has been adopted by the S. A. M. E. Sectional Committee on Plain Limit Gages. This temperature is coming more and more into use in this country and seems likely to be very generally adopted."

THE trials of the rigid airship R-80, which has been built by Vickers, Ltd., at Barrow, are now in progress. It will be recalled that some changes have been made in the structure of the airship since she was originally launched in July last. In the altered form she has a gas capacity of 1,250,000 cubic feet, a gross lift of 38½ tons and a disposable lift of about 17½ tons. The propelling power consists of four Wolseley-Maybach engines, each of 230 horsepower. Two of them are housed in the forward gondola and geared to a single propeller, the others being carried in single units in the wing gondolas. The R-80, at the cruising speed of 50 miles per hour, would have, it is estimated, a radius of 6500 miles. The R-36, which is being built at the Beardmore aerodrome at Inchinnan, is nearing completion, and will be ready for her trials in the course of a few weeks.

An Estimate and Analysis of Various Forms of Tractor Transmissions

Generally speaking, the smallest number of gear reductions is the best on tractor transmissions. The statement must be qualified, however, and this article discusses the advantages and disadvantages of the various types of gears. Several gear calculations are worked out by the writer.

By P. M. Heldt

TRANSMISSION losses are a small item in the automobile, as the average American passenger car runs upward of 90 per cent of the time on high gear, in which case the engine power is transmitted through only a single pair of gears. These gears, moreover, are cut very accurately, in order to insure quiet operation, and accuracy of tooth form at the same time insures high efficiency of transmission.

In a farm tractor, on the other hand, where the speed reduction between the engine crankshaft and the driving wheels is about ten times as great as in a passenger car, there are practically always several pairs of gears through which the power is transmitted successively before it reaches the driving wheels. The number of gear reductions and the arrangement of the gears are matters in regard to which a great deal of difference of opinion still persists. Generally speaking, the smaller the number of gear reductions the better, but the statement requires some modifications. The smallest number of reductions is the best only if it permits of safe maximum tooth pressures, gear wheels not too large in diameter so they can be fully enclosed, an adequate ground clearance, and a suitable location of the engine and power take off.

Representative figures determining the gear reduction required are as follows: Engine speed, 900 r.p.m.; drive wheel diameter, 54 in.; plowing speed, 2¾ m.p.h. The driving wheels of such a tractor would rotate at

$$\frac{2\frac{3}{4} \times 5280 \times 12}{54 \times 3.1416 \times 60} = 17.1 \text{ r.p.m.}$$

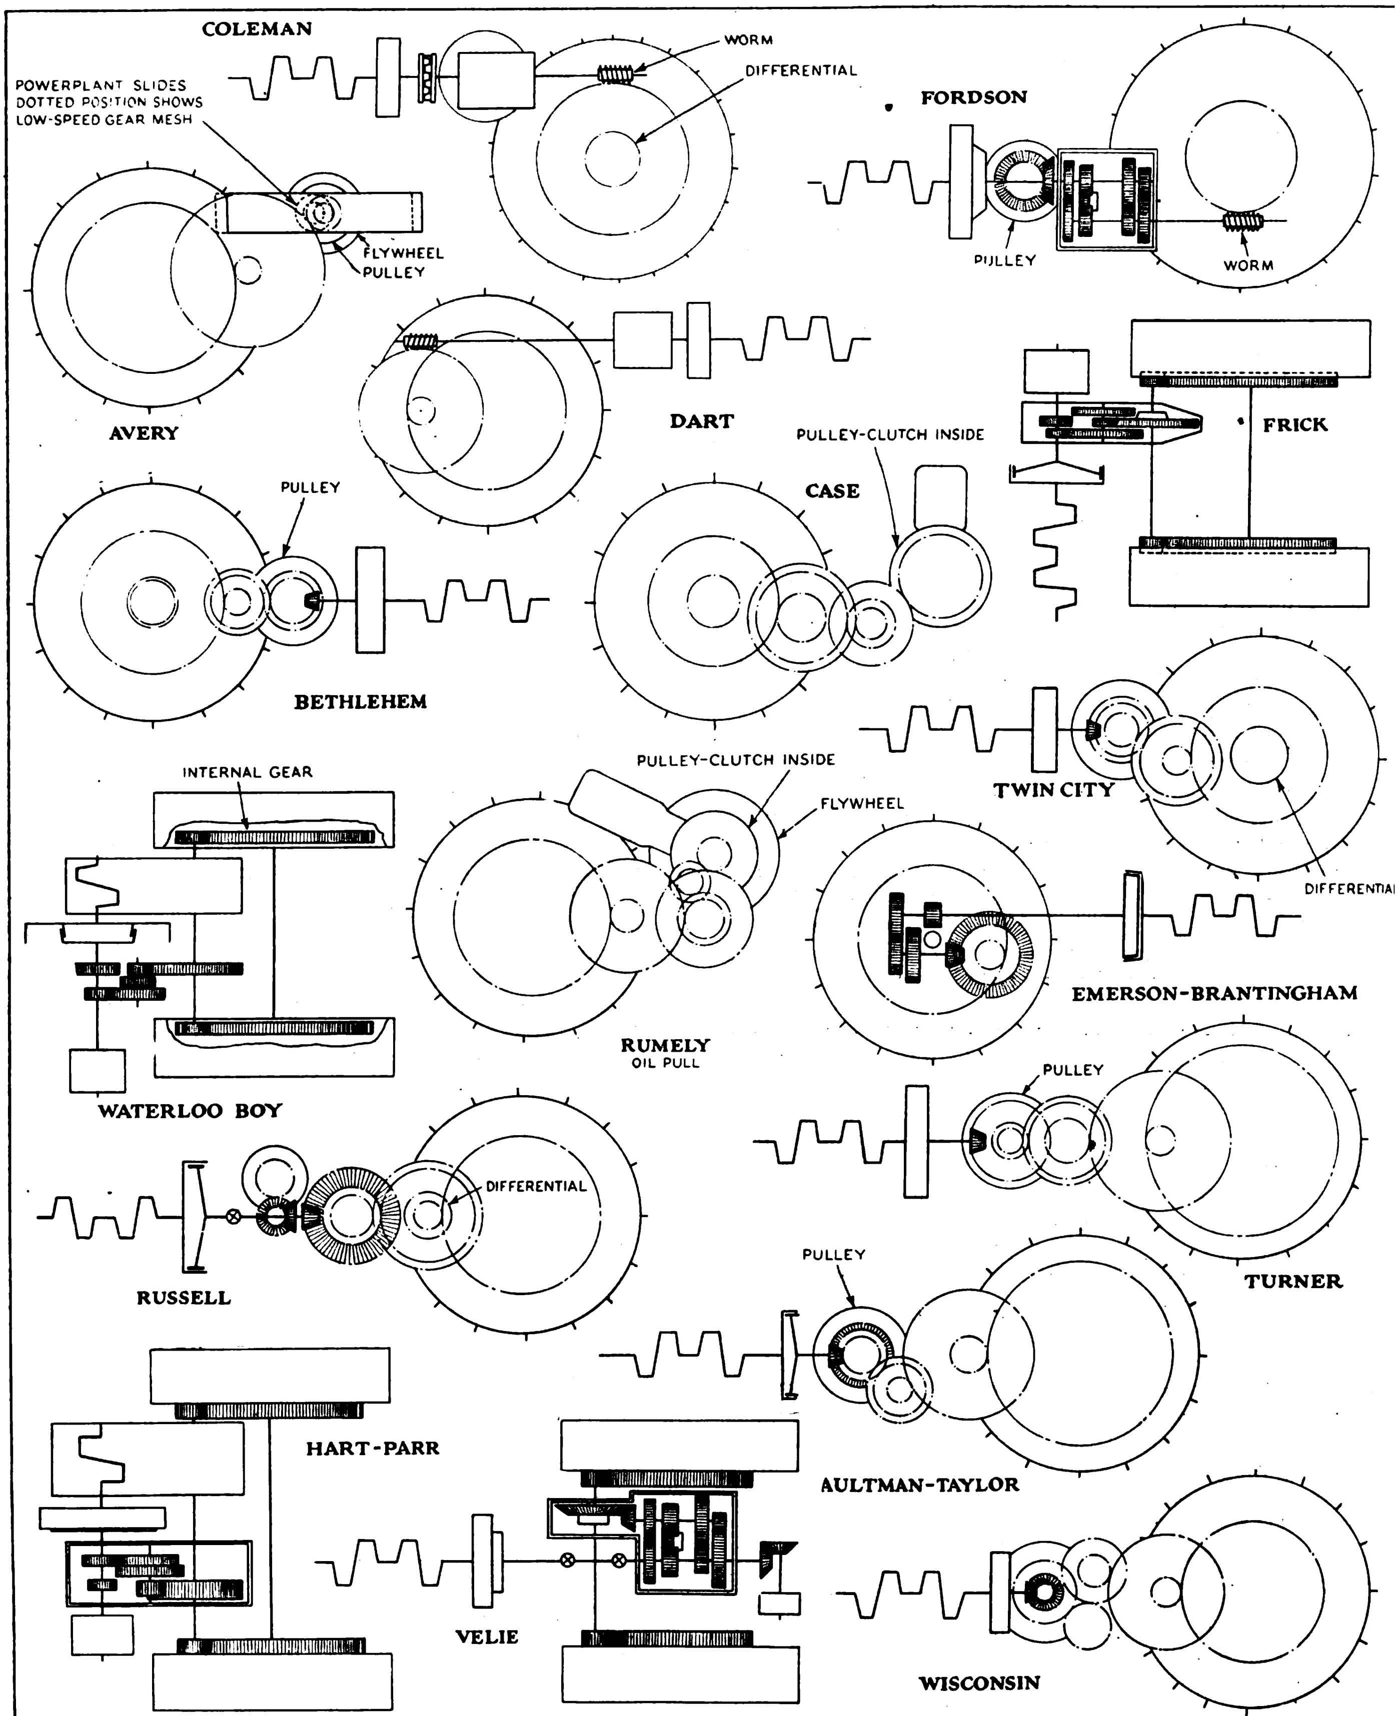
and the gear ratio therefore must be

$$\frac{900}{17.1} = 52.6$$

Such a large ratio can hardly be obtained in two steps by means of spur and bevel gears and where these types of gear are used exclusively it is customary to have three sets. This is the more necessary because the low speed, which is usually only about two-thirds the high, is obtained by the same number of gear reductions. This speed is sometimes as low as 1½ m.p.h. and then requires a speed reduction of nearly one hundred to one.

Almost all the known transmission devices are employed in tractors, including spur gears, internal gears, bevel gears, worm gears, roller chains and friction disks. Of these the spur gear is used most extensively, undoubtedly because it has a balance of advantages in its favor, when cost of construction, efficiency of operation and ease of mounting are considered. There is hardly a tractor that has not at least one pair of spur gears in its transmission train. Bevel gears are used where the power has to be transmitted between shafts at right angles to each other. They are considered as rather undesirable by some designers, and in order to obviate the need for them, four-cylinder engines are sometimes placed transversely across the tractor frame, giving rise to what is known as the all spur gear transmission. With twin cylinder or horizontal opposed engines the crankshaft naturally extends across the frame, while if a four-cylinder vertical engine is thus placed it gives the impression that the designer is going out of his way to avoid the bevel gears. There are three objections to bevel gears. In the first place, they cannot be cut as accurately as spur gears; secondly, they are more expensive to manufacture than spur gears, and, lastly, they create a great deal of end thrust which must be provided for in the bearing design. On account of the lesser accuracy of tooth form and the greater total bearing pressure, the bevel gear is undoubtedly slightly less efficient than the spur gear. Owing to the fact that bevel gears nearly always overhang their bearings, the radial loads of bevel gears usually are considerably greater than the loads due to corresponding spur gears. Where a pair of bevel gears is used it is not usual to obtain any great reduction in speed from it. Thus under certain conditions one more pair of gears may be required to obtain the predetermined reduction than if spur gears were used exclusively. Contrary to automobile practice, the bevel gearset is generally placed at the forward end of the transmission instead of at the rear end. The advantage of this is that the thrust loads to be provided for are very much smaller.

By the use of the worm and worm wheel for the transmission it is possible to locate the engine with its axis in a fore and aft direction and yet do without a pair of bevel gears. It does not matter whether the worm is the only transmission element, that is, whether a single reduction is used, or not. A single step reduction by worm and wheel is used in the Coleman tractor, a diagram of the transmission of which is shown on opposite page. In its earlier form the Coleman had only a single speed, the power being transmitted directly from the engine crankshaft through the worm and wheel to the rear axle. The present model has two forward speeds, the high speed being a direct drive and the low speed a back-geared drive. A transmission of this type has the advantage of great simplicity of construction and should be cheaper to produce than any other system. The tooth pressures undoubtedly are very high, and so also are the thrust loads which must be provided for. Neither the tooth pressure nor the thrust load is as great, however, as in a tractor with final drive by worm and wheel and a first reduction by some other form of gearing, for while the rear axle torque would be the same the worm wheel pitch diameter would be less in the double reduction drive. The double reduction transmission, including one reduction by worm



Diagrams of power transmission mechanism in different makes of farm tractors

and wheel, is used in the Fordson and several other tractors. In the Fordson the worm and wheel constitute the final drive, while in the others it constitutes the first reduction. The advantage is claimed for this latter arrangement that a worm gear is most efficient at high speeds, while a spur or internal gear is most efficient at low speeds of rotation. For a given horse power transmitted the tooth pressure is lower the higher the speed of the worm, and there is therefore less danger of forcing the film of oil from between the teeth of the worm and wheel. The rather low efficiency of the spur and internal gear at high speeds is due to inaccuracies in the form of the teeth which give rise to violent shocks at high speeds. A first reduction by worm and wheel and a second reduction by internal gears is used on the Dart tractor and a first reduction by worm and wheel and a final reduction by spur gears inclosed in the central case is used on the W-S-M and the Farquhar tractor.

Two step reductions with spur gears only are occasionally used, the Avery furnishing an example of this form of construction. This necessitates rather low engine speeds and large diameter gear wheels. For instance, if the engine speed is 600 r.p.m., the drive wheel diameter 48 in., and the plowing speed 2¾ m.p.h., the reduction ratio between engine crankshaft and rear wheels needs to be only a little over 31, and this can be obtained in two steps. The wheels, however, will be so large in diameter that it is practically impossible to enclose them, and tractors of the all enclosed type with spur gear transmission always have more than two steps to the transmission.

The three step reduction is undoubtedly the most popular type of transmission, being found in many different designs of tractors with both all spur gear and spur and bevel gear transmission. If there is any type of tractor transmission that may be said to be typical in that it is used on a greater number of designs than any other, it is the three step transmission with a first reduction by bevel gears and the other two reductions by spur gears. The sliding pinions are then mounted on the shaft carrying the wheel of the bevel gearset. This involves sliding the pinions on a transverse shaft, which is not quite as convenient as sliding them on a longitudinal shaft, but as the gears of a tractor are shifted only very rarely and then only while the tractor is stationary, this is not a serious objection. It is not an easy matter to get along with less than three reductions, unless a worm drive is used, because with spur and bevel gears the wheels become so large that it is practically out of the question to enclose them.

With a three step transmission the last set of gears may be placed either on the wheels in the form of bull gears, in which case they are, of course, either entirely exposed or only imperfectly enclosed, or else placed at the center of the axle and enclosed within the axle housing. The latter arrangement is being favored more and more, because exposed gears cannot be lubricated and wear out rather rapidly. In the former class with the final drive at the wheels must be included a few with exposed chain drive to the wheels.

After the three step transmissions come the four step, and these, too, are quite numerous, especially among the older designs of tractors. These tractors in a great many cases have wheels of very large diameter, and as they are intended for plowing at low speed they require a very large reduction ratio.

The accompanying sketches show diagrammatically the arrangement of the power transmitting members on a large number of American machines, including representatives of practically all types.

It has become very common to use teeth with 20 deg. pressure angle, tractor designers following automobile practice in this respect. The 20 deg. pressure angle has the advantage that there is less undercutting in the pinions, and consequently the teeth are much stronger. The Fellows stub tooth, in which the radial tooth elements are the same as those of a standard involute gear tooth of a diametral pitch two numbers higher, is probably most widely used, but there is also some call for full depth 20 deg. teeth, while recently an attempt has been made to standardize the depth of stub teeth at 0.8 the depth of standard 14½ deg. involute teeth.

Gear Calculations

In the selection of the pitch the designer does not have much guidance of a theoretical nature. There is, on the one hand, a leaning toward the finer pitches, because their use permits of a greater reduction being obtained by means of a single pair of gears. The minimum number of teeth in the pinion is more or less fixed, and the finer the pitch the smaller will be the wheel diameter for a given reduction ratio or the greater the reduction ratio for a given wheel diameter. On the other hand, a coarser pitch gives a stronger tooth. There should evidently be some relation between the pitch and width of face. If the width of face is exceedingly great it is impossible to obtain uniform tooth pressure over the entire width, and part of the faces may even be entirely out of contact. The best width is evidently the maximum for which fairly uniform contact is obtainable. If, with a certain pitch. the required width figures out greater than this, it is advisable to choose a coarser pitch, which will permit of a smaller face width. In industrial gear design it has been a long established practice to make the face equal to eight divided by the diametral pitch. It is believed that, owing to improvement in mounting practice since this rule was adopted, it is now practical to go to a face width equal to 10 divided by the diametral pitch. In automotive work the accuracy of mounting is certainly equal to that in the best industrial work and face widths as arrived at by the latter rule are not excessive. Ten divided by the diametral pitch is substantially equal to three times the circular pitch.

Let us assume an engine delivering 25 b.hp. at 900 r.p.m. This corresponds to a torque of

$$\frac{25 \times 33{,}000}{900 \times 6.28} = 146 \text{ lb.-ft.}$$

or

$$12 \times 146 = 1750 \text{ lb.-in.}$$

For the low speed a reduction ratio of about 64 to 1 may be required. This can be obtained in three stops so proportioned that the driven wheels will increase in diameter fairly gradually from front to rear. The first step is generally made rather small, one of the reasons being that the first reduction pair precedes the sliding gearsets, and the higher the reduction ratio the more difficult it is to slide the pinions on the splined shaft. A first reduction of 2 to 1 corresponds closely to current practice, and this leaves a total reduction ratio for the intermediate (low speed) and final reductions of 32 to 1. Both of these reductions may be made the same, or about 5⅔ to 1. Owing to the use of finer pitch teeth in the intermediate as compared with the final reduction gears, the intermediate wheel will have a diameter about midway between the bevel gear and the rear axle gear, thus giving a gradually deepening form of gearcase.

With bevel gears in automotive practice it is customary to make the face width equal to one-quarter the pitch line length. The maximum face length permissible in bevel gears is one-third the pitch line length, and somewhat smaller lengths are better because more nearly uniform pressure along the face of the tooth is assured.

A formula for the strength of bevel gears is as follows:

$$F = \frac{S L p y}{3}(1 - a^2)$$

where

F = the tangential force on the maximum pitch circle of the pinion.
S = the permissible stress in the gear teeth.
L = the pitch line length.
p = the circular pitch.
y = the Lewis constant for the number of teeth in the pinion.
a = the ratio between face width and pitch line length.

This equation can be transformed into a somewhat more convenient form.

Let

$c = (1 - a^2)$ = the face width factor.
v = reduction ratio.
n = number of teeth in pinion.
d = the maximum pitch diameter.

and

T = the torque to be transmitted, in lb.-in.

Then

$$\frac{Fd}{2} = T$$

and

$$F = \frac{2T}{d}$$

Also,

$$p = \frac{d\pi}{n}$$

and

$$L = \sqrt{(1/2)^2 + (v/2)^2}\, d = v d$$

Substituting in the above formula we get

$$\frac{2T}{d} = \frac{S \times \sqrt{(1/2)^2 + (v/2)^2}\, d \times d\pi \times y \times c}{n}$$

which simplified gives

$$T = \frac{S v d^3 y c}{2n}$$

The values of v, y and c can be obtained from the three tables herewith.

As the gears will be small in any case it is better not to use too small a number of teeth in this set. We will assume that the pinion has 18 teeth and the gear 36 to give the assumed reduction of 2 to 1. The stress in the teeth for heat treated gears may be taken at 16,000 lb. p. sq. in. Inserting values in the equation for strength,

$$1750 = \frac{3.14 \times 16{,}000 \times 1.12 \times d^3 \times 0.131 \times 0.193}{2 \times 18}$$

$$= 39.5\, d^3$$

$$d^3 = \frac{1750}{39.5} = 44.4$$

$$d = \sqrt[3]{44.4} = 3.54 \text{ in.}$$

This should be the maximum pitch diameter. As there are 18 teeth, the diametral pitch will be

$$\frac{18}{3.54} = 5.09,$$

which is very close to 5, and 5 pitch teeth must be used. The true maximum pitch diameter will then be

$$\frac{18}{5} = 3.600 \text{ in.}$$

The torque on the intermediate pinion shaft will be 3500 in.-lb. Taking the Lewis formula for gear tooth strength

$$F = S p f y$$

Here again

$$F = \frac{2T}{d}$$

and, substituting,

$$\frac{2T}{d} = S f p y$$

Also,

$$p = \frac{d\pi}{n}$$

and

$$f = 3p = \frac{3d\pi}{n}$$

Substituting again

$$\frac{2T}{d} = S \times \frac{d\pi}{n} \times \frac{3d\pi}{n} \times y$$

$$T = \frac{3}{2}\frac{S d^3 \pi^2 y}{n^2} = \frac{14.8\, S d^3 y}{n^2}$$

As stated above, $T = 3500$. Let $S = 16{,}000$ lb. p. sq. in. Assume $n = 12$. Then

$$3500 = \frac{14.8 \times 16{,}000 \times d^3 \times 0.104}{12 \times 12}$$

$$d^3 = \frac{3500 \times 12 \times 12}{14.8 \times 16{,}000 \times 0.104} = 20.5$$

$$d = 2.74$$

The diametral pitch would be

$$\frac{12}{2.74} = 4.38$$

Assume $n = 13$

Then

$$d^3 = \frac{3500 \times 13 \times 13}{14.8 \times 16{,}000 \times 0.111} = 22.5$$

$$d = 2.825$$

The diametral pitch would be

$$\frac{13}{2.825} = 4.60$$

Assume $n = 14$

Then

$$d^3 = \frac{3500 \times 14 \times 14}{14.8 \times 16{,}000 \times 0.117} = 24.8$$

$$d = \sqrt[3]{24.8} = 2.92$$

and the diametral pitch is

$$\frac{14}{2.92} = 2.92$$

Assume $n = 15$, then

$$d^3 = \frac{3500 \times 15 \times 15}{14.8 \times 16{,}000 \times 0.122} = 27.3$$

$$d = \sqrt[3]{27.3} = 3.01$$

and the diametral pitch is

$$\frac{15}{3.01} = 5 \text{ substantially.}$$

Any of the above pinions would do so far as strength is concerned but fractional pitches ordinarily are not used, and therefore the last mentioned should be chosen, that is, a pinion of 15 teeth and 5 diametral pitch. We have assumed that the face width is 3 times the circular pitch; hence

$$p = \frac{3.1416 \times 3}{5} = 1.88 \text{ in. } (1\tfrac{7}{8} \text{ in.})$$

The mating gear will then have

$$5\tfrac{2}{3} \times 15 = 85 \text{ teeth.}$$

The torque on the final reduction pinion will be $5\frac{2}{3}$ times as great as on the intermediate pinion. The necessary increase in strength will be obtained by increasing

the circular pitch, the pitch diameter and the width of face, each factor in the same proportion as far as possible. The multiplying factor therefore will be

$$\sqrt[3]{5.67} = 1.78$$

This would make the circular pitch

$$\frac{3.1416 \times 1.78}{5} = 1.12$$

The nearest standard circular pitch is 1.05 (3 diametral pitch). The face width is again 3 times the circular pitch which makes it

$$3 \times 1.05 = 3.15, \text{ say } 3.25 \text{ in.}$$

and since the product pitch diameter $\times$ circular pitch $\times$ face must be 5⅔ times as great for the final drive as for the intermediate pinion we have

$$3 \times 0.63 \times 1.87 \times 5.67 = x \times 1.05 \times 3.25$$

$$x = \frac{3 \times 0.63 \times 1.87 \times 5.67}{1.05 \times 3.25} = 5.86 \text{ in.}$$

Hence the number of teeth required would be

$$3 \times 5.86 = 17.6$$

However, owing to the much lower peripheral speed it is permissible to increase the stress in the metal from 16,000 to between 18,000 and 19,000 lb. p. sq. in., and this permits of the use of 15 teeth in this pinion also.

Federal Aid Roads Under Construction or Completed

OF the 22,030 miles of Federal aid roads which have been built or are now under construction, more than two-thirds are earth roads, sand clay, or gravel, says the chief of the Bureau of Public Roads, United States Department of Agriculture. These have cost less than one-third of the total amount expended, as compared with nearly 50 per cent of the estimated cost applied to 4890 miles of hard-surfaced roads. A study of local conditions by an engineer of the bureau is necessary before a road project may receive Federal aid.

The type of road to be used and the most suitable surface with respect to the traffic of the locality must be determined. Service must be satisfactory, while costs must be kept low, both for building and maintenance. There must be a careful analysis both of the engineering and economic conditions for each particular project. There are individual considerations in every case which affect the determination as to the best type of road materials for that locality.

The mileage of Federal aid roads which have been built or are now under construction is nearly sufficient to encircle the globe. This is the record of work accomplished since July, 1916, when the Federal Government first stepped in to aid in the enormous task of building highways that are now called upon to carry more than 9,000,000 motor vehicles plus a very substantial horse-drawn traffic in the forty-eight States. The Federal aid law is well named. The Department of Agriculture has given the broadest possible construction to the law for the purpose of providing the greatest mileage of highways suited to the traffic to be carried over them at the minimum expense. An analysis by the Bureau of Public Roads of the projects under contract shows that all types of roads, from the graded earth road up to the finest paved surfaces, have been built.

Use Many Kinds of Road Surface

Granting that the preparation of the roadbed has been properly done, many kinds of road surfaces will give excellent service. The element of time is important. There are so many miles of roads to be constructed and their cost will be so enormous that the most careful and detailed study of each road project must be made to provide, at the lowest possible cost, roads which will give satisfactory service and which can be maintained without undue depreciation under the traffic which is to use them. Many times the question has been asked the bureau, What type of road is best? The answer is always the same: There is no one best kind or type.

A recent statement issued by the officials of the bureau expresses this thought in the following language:

"It is the policy of this bureau to consider the conditions on each individual Federal aid project, as there are elements, such as subgrade, drainage and present and prospective traffic, which vitally affect the determination of the standards of construction to be used."

That is, there must be a careful analysis both of the engineering and economic conditions for each particular case to determine the kinds of materials that can be used successfully, and after these facts are determined then the various types of construction which can be used economically should be brought into competition to secure the best possible results. There have been occasional attempts to write into State laws or the governing conditions of bond issues a requirement as to the type or kind of roads to be constructed. To follow such a course would be most unfortunate.

The cost must always be considered in determining the type of road surfaces which are selected, and the allowable cost must be determined by the traffic which is to be borne. Local conditions vary to such an extent that very careful consideration must be given each project before determining the character or type of roads to be built. This principle was recently expressed to a chamber of commerce, asking for information, in the following language:

"Types of highways should not be specified by law. This is a matter to be decided by the State highway department, in which should be lodged full authority both to construct and to maintain. Competition between different types of material should be maintained and selection made to fit traffic requirements in each case. The bureau does not recommend any one type to exclusion of others."

Specification of Electroplating for the Automotive Industry

There is a need for scientific study of plating methods and of determining or specifying the quality of finished products. This article describes uses and technical details of electroplating and points out the possibility of cooperation between technical men and electroplaters.

By William Blum*

IT is safe to say that the prospective purchaser of an automobile gives less conscious consideration to the kind or quality of electroplating upon it than to any other single factor. And it is equally true that in most cases the electroplating has very little effect upon the actual period of possible service of the car. It is probable, however, that the general appearance of the electroplating may produce an unconscious effect upon the purchaser of a new car and certainly the condition of the plated metal parts has a very decided effect upon the appearance and salability of a used car.

One reason for the small amount of consideration that has been given to electroplating in this and many other industries is that this process has been looked upon as useful chiefly for ornamental purposes and its value for the prevention of corrosion has been almost overlooked. Even though electroplating constitutes a very minor part of the total cost of a finished car or airplane, it must be given greater consideration than heretofore if uniformly satisfactory products are to be obtained.

Choice of Plating

When electroplating is mentioned, nickel is the only metal which is considered by the average person and even by many engineers. There is a good reason for the extensive use of nickel plating, as this metal has a pleasing appearance and possesses to an unusual degree the property of resistance to tarnish under the usual atmospheric conditions. It is reasonable, therefore, that wherever appearance is a primary consideration nickel plating should be employed, as indeed it is on many exposed parts of automobiles. Where the base metal is of brass it is probable that no other coating than nickel need be considered in the automotive industry, unless it is necessary to avoid the presence of bright coatings as in military airplanes.

With steel parts, however, it is very essential that they be protected against corrosion, especially if they are relatively inaccessible and are not intentionally or incidentally coated with a film of oil. Where steel parts must be protected and where appearance is not a primary consideration, all experience indicates that zinc coatings should be given preference. The value of zinc for this purpose depends upon the fact that when zinc and iron are in contact in the presence of moisture, the zinc is the more readily corroded and by virtue of this property it prevents the iron from corroding. This difference in the susceptibility of metals to corrosion is connected with their relative positions in the electrochemical series, in which zinc is above iron. If, on the other hand, iron is in contact with copper under similar conditions, the iron is more readily corroded than the copper (which is below iron in the series) and the presence of the copper actually accelerates the corrosion of the iron.

Nickel behaves somewhat similarly to copper, but, fortunately, its electrochemical potential is closer to that of iron than is the potential of copper, and, consequently, the presence of nickel does not appreciably accelerate the corrosion of the iron, although it does not prevent such corrosion if the iron is exposed.

The question as to which kind of plating should be employed in any particular case depends very largely upon the purpose for which the articles are to be used and the degree of exposure to which they may be subjected. This problem of the proper choice of protective coatings for iron and steel received very serious consideration during the war, and extended investigations were carried out upon it at the Bureau of Standards. The results of these tests are summarized in Circular 80 of the Bureau of Standards upon "Protective Metallic Coatings for the Rustproofing of Iron and Steel." During the war a suggested classification of protective coatings on military supplies was proposed by the Bureau of Standards[1]. In this proposed classification the four principal groups of present interest were as follows:

(1) Metal requiring protection only during storage or transportation, for which the application of grease or slushing oils was recommended.

(2) Metal for indoor use or for mild exposure, or which can be frequently cleaned and oiled. For this purpose almost any protective coatings that furnish the desired color, appearance and resistance to abrasion might be employed. Among the processes used are various kinds of plating, and the different chemical finishes including the oxide coatings such as blueing and browning, and the phosphate finishes such as the Parker Process.

(3) For steel subject to moderate outdoor exposure or which it is desired to salvage, light zinc coatings were recommended.

(4) For steel exposed to severe outdoor or marine conditions relatively thick zinc coatings should always be employed.

If an attempt is made to apply such a classification to the automotive industries it is necessary to distinguish between the passenger car in which consideration must

*Chemist, United States Bureau of Standards. Published by permission of the Director of the Bureau of Standards.

[1] Military Applications of Electroplating, by William Blum. Transactions of the American Electrochemical Society, 34, page 169, 1918.

always be given to appearance, and the motor truck or airplane in which strength and durability are the principal considerations.

In general it may be stated that for the first group nickel plating must be employed on all prominently exposed parts, but zinc coatings should be specified for those parts which are not exposed or which can be covered with a suitable paint or enamel. As an instance of the latter application may be cited the almost universal use of zinc plating (electrogalvanizing) in the manufacture of rims. For auto trucks and airplanes zinc should be used almost exclusively. In spite of the superior value of zinc in furnishing protection against corrosion it has been only within recent years that its use for many purposes has superseded that of nickel or the still more objectionable copper coatings. It is interesting to note that during the early part of the war practically all airplane parts were copper plated, and it was not until near the conclusion of the war that zinc plating for this purpose was adopted by the Navy Department and subsequently by the War Department. Even since that time, however, many airplane manufacturers have continued the use of copper and nickel plating, and in one case within a year the author has seen a new airplane in which steel parts in immediate contact with each other were coated with four different metals, namely, copper, nickel, zinc and tin, although zinc might have been used to advantage on all!

Practically the only extended application of copper plating in the automotive industries is in connection with case hardening where it is employed to protect certain parts of the steel from the hardening action. The use of copper plating preparatory to nickel plating is not necessary and there is no evidence to show that steel plated with these two metals is any better protected against corrosion than if plated properly with nickel alone. In some cases the presence of the copper may actually accelerate corrosion of the steel when the latter is exposed by abrasion.

Sometimes copper coatings are deposited previous to nickeling in order to furnish a surface which can be readily buffed to a high finish. A good illustration of this use of copper plating is in the manufacture of lamp reflectors which, if made of steel, are successively plated in the following baths:

(1) cyanide copper,
(2) acid copper (and then buffed),
(3) nickel, and
(4) silver, after which they receive the final buffing.

Owing to the fact that zinc does not possess a pleasing appearance, and that it readily tarnishes and turns white on exposure, various methods have been proposed for covering the zinc coatings. Nickel plating over zinc plating is sometimes carried out successfully, but even in those cases where initially adherent deposits of nickel are obtained, there is a marked tendency for the nickel to peel subsequently if the zinc is exposed either through porosity of the nickel, or its abrasion. Although paints and enamels do not adhere well to hot-galvanized surfaces, good adhesion is usually secured upon the zinc plated or "electrogalvanized" surfaces. Where the enamels are to be baked, it is frequently advantageous to heat the zinc plated articles to the temperature of the enameling ovens for a short time in order to expel any occluded gases or moisture. After the parts are cool the enamels are applied as usual and baked. By this method the chance of "blistering" of enamel is reduced.

Basis of Specifications for Plating

Having determined what kind of plating shall be used for a given purpose, it is possible to specify or control the quality of the product by either or both of two methods, which depend respectively upon:

(1) the definition of the details of the process to be employed to insure a satisfactory product; or

(2) the specification of certain properties in the finished product.

From the standpoint of the purchaser or user of equipment it is entirely immaterial what process is employed to yield a certain result, provided only that the product has the desired properties. In general it is preferable to avoid specification of process details, both because such a procedure tends to decrease the responsibility and initiative of the operator, and because it is practically impossible in the present state of the electroplating industry to predetermine or control the exact conditions of operation.

From the standpoint of the factory engineer, however, it is often essential to consider the details of the process in order that those conditions may be selected which will yield a product to meet any specified requirements. In attempting to fix the conditions for plating, every effort should be made to foster co-operation between the technical staff and the plater. There is to-day a great need and demand for reliable information upon plating operations, which can be met only by the harmonious cooperation of engineers and chemists with the electroplaters. The American Electroplaters' Society, composed of foreman electroplaters, is working diligently to advance the state of this industry and will welcome advice and assistance from all interested.

Methods of Plating

It is not within the province of this paper to discuss in detail the methods to be employed in plating, but it may be of interest to point out the various factors which may determine the quality of the product.

In general the **cleaning** of metal preparatory to plating is very essential to the production of adherent or impermeable deposits. The cleaning operations usually consist of the removal of grease by means of suitable alkaline solutions and the removal of oxide or scale either by pickling or by mechanical processes, such as sand blasting. In cases of defective plating the cleaning operations should be carefully investigated in order to determine whether they are effectively carried out.

The **composition** of the plating solutions may have a very direct bearing upon the quality and particularly the uniformity of the work. In zinc plating, satisfactory results can be obtained both from sulphate and from cyanide solutions, although the latter usually possess better "throwing power," i.e. ability to plate in deep recesses. The basis of practically all nickel plating solutions is nickel sulphate, which may be supplied either as such in the form known as "single salts" or in combination with ammonium sulphate to form the so-called "double salts." The beneficial effect of boric acid in yielding brighter deposits is probably due to the maintenance of a slight acidity in the solutions. Ammonium chloride or sodium chloride is frequently added for the purpose of assisting in the corrosion of the nickel anodes, especially if they have a high nickel content.

The composition and physical condition of the **nickel anodes** must be considered in connection with the composition of the solution. Practically all the anodes used at present are cast anodes which contain iron and carbon, frequently added intentionally to facilitate casting and the subsequent solution of the anode.

The **temperature** of the plating bath may have an appreciable effect upon the character of the deposit. In general, deposits produced from warm baths are slightly coarser grained and softer than those from baths

at ordinary temperature. In the case of nickel, warming of the baths may be advantageous in removing the tendency to brittleness of the deposits which is frequently observed. Until recently most electroplating baths were regulated by controlling the voltage. More satisfactory results are obtained by the use of ammeters and the adjustment of the current to produce a certain current density (e.g. amperes per square foot) upon the work. By control of the **current density** and the **time of deposition** the average thickness of the deposit can be regulated. It is not now possible to specify even the desirable limits of all of the above factors in the operation of plating baths, but engineers or chemists who are called upon to assist the electroplater should pay attention to all of these points and determine if possible the optimum conditions for any given class of work.

Specifications and Tests

The usefulness and durability of any plated coating such as zinc or nickel depends upon a number of factors, among which may be mentioned the thickness, distribution, permeability, adhesion and hardness. Unfortunately it is very difficult to measure any of these properties directly. The total amount of metal coating upon a surface may be determined by suitable stripping methods, and the **average thickness** computed. Zinc coatings can be readily removed by the use of hydrochloric acid containing antimony chloride, which latter substance gives rise to the deposition of antimony upon the steel as soon as all of the zinc is dissolved and thereby prevents action of the acid upon the steel.

It is more difficult, however, to secure any solution which will remove nickel quantitatively from steel. For this metal, therefore, it is usually necessary to dissolve off the entire coating together with an appreciable amount of the base metal and to determine the nickel content of the solution thus obtained. In any case, by this method of procedure only the average thickness can be computed and no indication is obtained regarding the uniformity of distribution, or the possible porosity of the deposit. The actual measurement of the thickness of the coating by microscopic examination of the cross section is useful in research work, but is entirely impracticable as a basis for regular inspection.

Specification of the average thickness of the deposit does not insure a satisfactory quality; nevertheless, it is desirable within the factory to define and control the average thickness, in order to secure a consistent product. If **uniformly distributed** and free from pin holes it is probable that nickel coatings with an average thickness of 0.0005 in. will meet all ordinary requirements. To produce this thickness will require approximately 10 ampere-hours per square foot; this may be secured by using 10 amperes per square foot for one hour, or 5 amperes per square foot for two hours. The actual thickness of nickel plating in one plant was much less than 0.0005 in., although the engineer in the plant felt quite confident that at least 0.001 in. was used! For ordinary purposes zinc coatings of 0.0005 in. are usually sufficient, although for extreme exposure 0.001 in. is desirable. For a thickness of 0.0005 in. of zinc about 8 ampere-hours per square foot are required. For very accurate work, an allowance should be made on dimensioned or threaded parts for the thickness of the plating.

The methods which have been used for determining **the distribution** of the deposit depend essentially upon treatment with some reagent which will dissolve the coating and will give an indication when the underlying steel is exposed.

The most commonly used test for zinc coatings is the so-called "Preece test" in which the objects are immersed in a neutral copper sulphate solution for successive periods of one minute each until an adherent coating of copper is obtained on any part of the object. Although this method is useful for distinguishing roughly between different samples of similar material, its value is limited by the fact that the rate of reaction of the copper sulphate is influenced by the structure and purity of the zinc coating, and consequently misleading results may be obtained, especially in comparing samples produced by different methods—hot dipping, sherardizing and electroplating. There is need for the development of a similar method for determining at least the relative thickness of nickel coatings.

The **permeability** of coatings may be determined by the use of suitable reagents which will indicate whether at any points the underlying steel is exposed. The most common of these tests is the so-called "ferroxyl" test which is used in various modifications, but in each case depends upon the detection of exposed steel by means of ferricyanide. Thus, if nickel plated steel is treated with a solution containing 1 per cent of potassium ferricyanide and 2 per cent of sulphuric acid, blue spots will appear very quickly at any points where the steel is exposed. This test may also be applied for determining the permeability of coatings of copper, lead, tin or other metals which lie below iron in the electrochemical series, but is not applicable to the testing of zinc-coated steel.

A suitable **corrosion test** may prove more useful in determining the value of protective coatings than any of the specific tests above mentioned. The ideal corrosion test would be based upon exposure to actual conditions of use. Such a test would require, however, so long a period of observation that the results would not be of value in determining the quality of any particular lot of material. In consequence various "accelerated" tests have been proposed. When an accelerated test such as the salt spray or moist air test is used, the question is frequently asked as to the interpretation of the results in terms of ordinary exposure. Any attempts to make such a co-ordination must be only approximate because there is no such thing as "ordinary exposure," as the climatic conditions throughout the country and in different cities vary greatly.

The **salt spray test** which has proven to be especially useful for testing zinc coatings, depends upon the exposure of the articles to air containing in suspension a spray of 25 per cent sodium chloride solution. The articles are examined at frequent intervals and the time when iron rust first appears is taken as an indication of the failure of the coating. Details of this test will be found in Circular 80 of the Bureau of Standards.

In using such a test as the basis of specification for zinc coatings it is customary to state the length of time which the objects must withstand corrosion.

For ordinary usage on automotive equipment it is probable that zinc-coated material which will stand up for two days in the salt spray test will be satisfactory, although for equipment to be used in a marine atmosphere or under particularly severe conditions this time of exposure may be increased to three or four days.

Unfortunately the salt spray test is not well adapted to the examination of nickel coatings since the latter do not exert intrinsic protection of the steel and in consequence if the base metal is exposed at any point corrosion will occur within a very few hours in the salt spray test. Exposure to air saturated with moisture at slightly elevated temperatures has in some cases proven useful for detecting porosity in nickel coatings on steel, but it has no value in determining the thickness of the coating. At the present time there is practically no satis-

(Continued on page 1293)

Methods of Cooling Airplane Engines

Water cooling, as applied to aircraft engines, is far from fully developed. While direct air cooling will improve, water cooling will improve as well. This article indicates the lines along which development may be expected to progress and discusses developments likely to come.

By A. Ludlow Clayden

DESPITE recent advances in the air cooling of aviation engines there seems but small probability of the early abandonment of water cooling and this is the easier to understand when it is remembered that the basic principles of the two systems are identical.

In both cases the heat originates in a small volume, and is applied to a small surface; that is, to the cylinder walls and heads. The problem is to cause the heat to flow away from these points rapidly enough to keep them at working temperature. Air has a low specific heat and to carry off a large quantity of heat from metal, a large volume of air must be brought in contact with it, because air is a very poor conductor and must actually be made to touch the metal if it is to have a cooling action.

In order to utilize an adequate volume of air, the heat from the cylinders must be carried by conduction and "spread" over a larger surface. By adding fins to a cylinder its surface is increased and heat flows from the cylinders into the fins by direct conduction. By adding a radiator to an engine the cooling surface is increased in just the same way, but heat is transferred to the larger surface by the water instead of by direct conduction.

It is mechanically difficult to apply a sufficient increase of surface in the form of fins to a cylinder, and it is particularly difficult to care for the hottest parts such as the exhaust valve seatings, because of the presence of the valve operating mechanism and similar parts. Hence nearly all air cooled engines hitherto made have been forced to employ a lower mean effective pressure than is practicable with water cooling, so as to keep down the maximum temperatures in the cylinder. Allowing for a slight drop in m.e.p., for the weight of the fins and for the need to arrange cylinders radially or in some other unconventional way, means that the advantage of direct air cooling from fins over indirect air cooling from a radiator and a water content is not so great as it at first apparently ought to be.

In comparing air and water cooling it is seldom realized that water cooling as applied to aircraft engines is far from fully developed; that while direct air cooling will improve, water cooling also will improve, and that the weight of a water cooling equipment is a long way from the possible minimum.

F. W. Lanchester in his 1916 paper on engine cooling, which has been so much quoted, states axiomatically almost, that one square foot of radiator surface is necessary per brake horsepower of an aviation motor. This was only between four and five years ago, but to-day plenty of our military aircraft are operating with half a square foot per b.h.p., or even less and the head resistance of radiators has been cut down very greatly also.

It is not the writer's present purpose to go deeply into the subject, but merely to indicate the lines along which development has progressed and may be expected to progress still further. First, it has been discovered that the nose position which was almost always used a short time ago is a poor position from the viewpoint of efficient radiation. Owing to the interference of the propeller the air speed through the radiator on the nose of the fuselage averages around half the speed of the plane itself and is seldom more than 75 per cent thereof. This means that the radiator has to have greater developed surface than if it were subject to the full draft of motion of the plane, because the volume of air brought against the radiator increases almost directly with the speed of travel.

Nor is this all, for it has been found that by selecting proper locations on the side of the fuselage, in the slip stream of the propeller, a radiator can be put where it will be subject to an air speed greater than that of the plane by as much as 25 per cent.

Practically all airplane radiators are built up of thin copper tubes, honeycomb fashion, because this type of core is far the strongest in proportion to its weight at present known. The length of these tubes has to be in proportion to the air speed. With a low air speed the air is heated up a greater number of degrees per inch of travel than at a high speed, of course, and with most nose radiators a five inch tube is long enough to heat up the air to a point where it is so near the water temperature that its cooling value is small. With slip stream positions, tubes nine inches long can be employed and their last inch will be just as efficient as the last inch of the shorter tube in the nose radiator.

Thus for a slip stream radiator we need less total surface, because the air speed is higher, which means that we need less frontal area. Also, because the air speed is higher, we can use a deeper core, which again reduces the frontal area for a required developed area. The resistance to air flow of a 9-inch core is less than twice that of a 4½-inch core, so by using the slip stream position we reduce, first of all the total surface; that is to say the weight, and secondly, the head resistance in a still greater proportion.

Now, of course, the head resistance of a radiator in the high air speed of the slip stream is greater than it would be for the same radiator in the lower air speed around the nose, but this offsets only a portion of advantages gained. A still further offset arises from the fact that the nose of the fuselage can be made of a good stream line contour when there is no radiator, and this reduces the resistance of the airplane as a whole.

Yet another point of importance is that the airplane radiator has to be built large enough to cool the motor during climbing when the speed is low and the power output at a maximum. When altitude has been attained, due to the increased speed and smaller power employed, the amount of radiation needed is greatly reduced. This is cared for, in the case of nose radiators, by mounting shutters in front and closing them for a very large part of the flying time. These shutters increase the head resistance

quite substantially and are therefore a drawback. With a slip stream mounting it is quite possible to arrange a shutter in the form of a door opening outwards from the side of the fuselage and, if the hinge is forward, this door will cover up any desired part of the radiator while presenting a partially stream lined form; so that the power wasted by closing off this part of the radiator is reduced.

There have been several schemes, some of which are apparently satisfactory, for so locating the radiator so that it projects more or less from the side of the fuselage.

Coming back to the pure efficiency of a radiator, it is not generally appreciated to what an extent this efficiency is affected by the speed with which the water flows through it. The total amount of heat which can be dissipated by a given radiator may vary as much as 30 per cent, according to whether the water is flowing very slowly or very rapidly. There are two reasons for this, the most important is that turbulence in the water is necessary if it is to transfer all its heat content to the copper of the radiator, because water is a poor conductor. Secondly, the amount of heat dissipated by a radiator varies directly with the difference between the air temperature and the mean temperature of the radiator.

Taking an example—suppose a hundred pounds of water per minute enters the top of a radiator at 200 deg. and leaves the bottom tank at 150 deg., then the mean temperature of the radiator is 175 deg. and the b.t.u. lost per minute will be 5000. Let us now suppose that the water flows at 500 pounds per minute, then to dissipate the same amount of heat, we shall only need a temperature drop of 10 deg. This would mean that the average temperature of the radiator would be 195 deg. instead of 175 deg. In other words, we should have increased the mean difference between the air and water by 20 deg. Suppose the original radiator was designed to operate with an air water difference of 100 deg., by using the higher water flow we can cut down the size 20 per cent because we would have increased the difference to 120 deg.

The amount of water which will flow through a radiator depends upon the head. In a nose radiator this can only be a few inches. If a powerful pump is used which actually sucks on the radiator, the pressure in the suction line can be reduced to a point where the boiling point of the water will have been reduced enough to cause trouble with steam in the pump. Thus we are very definitely limiting the speed of the water circulation by the available head of water above the radiator. If, now, a radiator is mounted low down on the fuselage, the outlet from the motor can easily be two or three feet above the core, which is enough to give the most rapid flow that can be desired.

Summing up the advantages of slip stream mountings—we get a lighter radiator, a radiator with less head resistance, a radiator containing a smaller weight of water, and a radiator that can be shuttered with but small increase in resistance.

Enough has been said to bring out the point which the writer is anxious to make clear, namely that while air cooling has developed, water cooling has by no means stood still. The very brief summary of the advantages of the slip stream position only touches upon *one* of the ways in which the improvement of water cooling has been made and still is possible. There are many other things which affect it. Engine and plane designers both desire to save weight and to reduce resistance.

Many of them at the present time, through lack of appreciation, are not taking advantage of the fact that the scope for improvement in water cooling is almost as great as in direct air cooling.

Specification of Electroplating

(*Continued from page* 1291)

factory method for determining the quality of nickel coatings and much investigation may be required to develop suitable specifications.

The proper **adhesion** of coatings, especially of nickel, is of importance on parts such as bumper bars, that may be subjected to slight bending or deformation, which will cause cracking or peeling if the coating is not adherent. Upon thin sheet metal it is possible to make simple bending tests to determine the degree of adherence of the coating, but for the actual plated parts it is difficult to prescribe any generally applicable test. Where improper adhesion is suspected, scratching with a knife may be useful in order to determine whether the coating can be peeled off.

The **hardness** or resistance to abrasion is difficult to measure or specify since there are no satisfactory methods of determining the hardness of very thin sheets of metal. It is doubtful, however, whether in most cases the actual hardness of the deposit exerts much effect upon its period of useful service, except where the nickel plated articles are subjected to severe abrasion or to frequent cleaning, perhaps with unnecessarily harsh abrasives. In many respects a relatively soft deposit of nickel is preferable, since it is more readily buffed to a high polish.

Needs and Possibilities for Investigation

From the previous discussion it will be apparent that there **is a great need for** scientific study both of methods of plating and of determining or specifying the quality of the finished products. The satisfactory solution of these problems will require extensive research which must involve not alone laboratory studies but also the co-ordination of the results with plant practice and with service conditions. For a number of years investigations upon electroplating have been carried out at the Bureau of Standards with the co-operation of members of the American Electroplaters' Society.

The work thus far conducted has been of restricted scope, however, owing to the limited funds available and to the fact that much of the work has been conducted with reference to the specific needs of the government departments. At present a movement is on foot to secure more direct co-operation and actual financial support from manufacturers interested in electroplating in order that these investigations may be conducted more actively. The Research Extension Division of the National Research Council is co-operating in a plan to bring about greater support for this work. **Those engaged in or interested in the automotive industry will no doubt lend their efforts to the support of this plan for extension of research in electrodeposition, a field which has so many commercial applications.**

TECHNOLOGIC Paper No. 170, "Pyrometric Practice," issued by the Bureau of Standards, is now available. The publication has already been adopted as a text for teaching pyrometry in several universities. Copies may be purchased from the Superintendent of Documents, Government Printing Office, Washington, D. C., which publishes a list of other useful technical papers.

Present Problems of Marine Motor Design

The marine engine designer faces many problems not met by the automobile engineer. Tendency is to reduce number of models. Propulsion and flexibility are important unsolved problems. This article discusses present problems and points to future developments.

By William B. Rogers, Jr.*

IN comparison with the motor boat engineer, the automobile designer has had a pretty straight and well-defined path to follow. The early motor cars, pioneer vehicles of the present great industry, were truly "horseless carriages." So, too, is the most modern of cars. The wheelbase of the present motor car is not very different from that of the old-time barouche; the tread is the same. This must be the case from the character of the roads. If cars were to be built much longer there would be difficulty in negotiating turns, and if they were made even slightly wider, passing would be impossible on many roadways, and there would be trouble in getting through rough and rutty places which still exist in the remote regions.

So even the smallest and the largest chassis are relatively close together as to size, and the motors which drive cars do not cover a great range of weights, powers and dimensions. It has been possible therefore for automobile engineers to concentrate upon a pretty well-defined problem, to work out standards, to perfect detail, to effect refinement throughout the motor car.

The term motor car pictures a very definite thing to every man, woman and child throughout the civilized world. But a motor boat! If a friend should invite you to take an afternoon run in his motor boat, would you have any way of knowing whether you were going out in a 14-ft. glorified skiff or in an 80-ft. or 100-ft. cruising yacht? And the little 14-footer might be powered with a tiny single cylinder, two-cycle 2-hp. motor giving it a speed of 6 miles an hour, or equipped with a light-weight, high-speed 30-hp. motor capable of driving the planing hull at 25 miles an hour or more. Likewise, thinking about the 80-ft. yacht, she might be driven by a heavy-duty, slow-turning oil-burning motor, running at about 240 r.p.m. and weighing several tons, or the yacht might be of the express cruiser type, equipped with a couple of 200-hp. high-speed motors turning the propellers 1400 or 1500 r.p.m. and weighing less than 1500 lb. for each motor.

The very nature of things makes the marine field as much broader than the motor car field as the expanse of the waters is broader than the roadway. And another thing that we must remember is that the marine motor operates under full load all the time. Resistance of the water is constant at a given speed, except in the case of a hydroplane, and even in these boats the load is practically constant.

Ten years ago many of the marine motor manufacturers tried to build a range of models which would enable them to meet the requirements of as many types and sizes of boats as possible. It was then not unusual for the marine motor manufacturer to produce a line of motors comprising from twenty to fifty models. To be sure there would be a one, a two, a three, a four and possibly a six-cylinder, all of the same bore and stroke. But each of these motors would be an individual job as to base, manifolds, crankshaft, oiling system, etc., only the actual cylinders being identical. There are still several marine motor manufacturers who build thirty or more models.

The present tendency, however, is all the other way. Marine motor manufacturers, beginning about six years ago, just prior to the war, began to appreciate the advantages arising from concentrating upon fewer sizes. Several, indeed, have gone so far as to build one size only, a model designed to provide power for boats of a popular kind and size, so that demand would be assured. It is needless to dwell upon the advantages of this tendency; the great economies in production through proper shop equipment to turn out the fewer models, etc.

In the beginning the two-cycle motor was in the ascendancy in the marine field. That was when the average motor boat was a small craft and the average marine motor developed from 3 hp. to 10 hp. In these sizes the two-cycle motor still retains its popularity, not alone for pleasure boats, but especially for powerplants for small work boats, such as those used by fishermen of the New England Coast, Chesapeake Bay and the Great Lakes. The two-cycle motor is practical, particularly in single-cylinder and two-cylinder types, because its small first cost, its simplicity and the fact that lubrication can be accomplished effectively by mixing oil with the gasoline in the fuel tank compensate for the somewhat greater fuel consumption and the less easy starting of a two-cycle as compared with the modern four-cycle. The two-cycle motor has a real field in marine service, and because of its having been restricted to the smaller sizes it has become pretty well standardized.

Standardization Efforts

This is not the case with four-cycle marine motors. Through the Motor Boat Division of the Society of Automotive Engineers, however, much good work in the direction of standardizing marine powerplants has been accomplished and is being accomplished. The standardization of such features as carbureter flanges, mountings for electrical equipment, shaft tapers, etc., will simplify the problems of the marine motor designer and manufacturer.

About three years ago the writer, with a number of others concerned with the motor boat field, reached the

*Managing Editor, Motor Boat.

conclusion that to effect anything worth while in the industry, the situation must be attacked basically: That before marine motors and marine equipment in general could be standardized; before marine motors could be built in quantities by production methods, motor boats themselves must be standardized. By standardization in this sense, I mean developing boat models of popular size and type, both cruisers and runabouts, that can be built as stock jobs and sold in quantities as complete, ready-for-service craft.

Already a great deal has been accomplished in this direction. There are at the present time about thirty boat-building organizations which turn out standard stock models, and the number is increasing steadily. In another year or two, I believe, the majority of motor boats built in the United States will be stock models. When that is the case, the marine engineer will have a much more definite range within which to work. He will know the motor sizes upon which he can concentrate his energies with profit, and will be able thus to confine his efforts to the refinement and improvement of marine motors in the same general way in which the engineer in other automotive lines has worked with such remarkable results.

Propulsion Problems

There is another problem, or rather another series of problems which confront the marine engineer which fortunately for the automobile engineer never arise in his work. That is the matter of propulsion. In a motor boat installation all features of hull design and powerplant, including, of course, the propeller itself, are naturally correlated. The heavy hull designed for slow speed, such as that of a motor houseboat or a tug, must be powered for greatest efficiency with a heavy, slow-turning motor. The reason is that a high-speed motor, turning the propeller at high revolutions, would waste power tremendously through slip of the screw propeller.

To be able to determine the proper installation of power for a boat we must know all the factors: the form of hull, the speed for which it is designed, the weight and—at least approximately—the surface resistance. With this data available we can determine the proper power, the correct size of driving shaft, the size of the propeller as to diameter and pitch—the advance of each revolution of the screw, etc.

A nice engineering problem enters into the designing of every properly constructed motor boat, and that is a prime argument in favor of the standardization of motor boat models. It is, of course, no greater engineering task to design a complete model for duplication by the hundreds than it is to plan a single boat of the same characteristics.

Flexibility

Here is another problem that the marine engineer has been called upon to work out: The boat and its power installation have been designed for a certain efficient running speed, under full load. In the case of most motor boats it is impractical to provide for anything other than direct drive, because of mechanical complications, and losses of power where gear drives are employed to reduce or increase propeller speed with relation to the speed of the motor. But take the case of a motor boat of the cruiser class designed to make somewhere around 12 miles an hour. At times it will be desirable to operate this boat at speeds as low as 3 or 4 miles an hour, as in the case of fishing with trolling lines, when maneuvering and so on. The usual boat is equipped with a reverse gear giving direct drive forward, a neutral or idling position and driving at 60 to 85 per cent motor speed when in reverse.

Since the operator will not always desire to drive the boat at its maximum speed, we must have flexible motors, and the problem is to design powerplants which can be throttled over as great a range as possible without the danger of stalling or causing backfires. A number of devices have been perfected which accomplish this result quite well, but flexibility is still one of the problems which must be met by the marine engineer, notwithstanding the great improvements in carbureters during the past few years. The successful marine motor designer must study with the utmost care such matters as manifold design, lubrication which will be as effective at low speeds as at high speeds, gas speeds, the heating of the firing mixture, etc.

In the light of these things it is to be expected that the manufacturer of marine motors, having built a line of motors which have given satisfactory service over a period of years, will go about making changes slowly and will be cautious in attempting anything radical.

Cooling Difficulties

There is one feature which seems on the surface to make the task of the marine motor engineer comparatively simple, and that is the matter of cooling. In a boat there is always plenty of water for the circulating system, and all we need is a pump of some kind to force the water through the jackets. We can even use part of the discharged cooling water to help cool and silence the exhaust. Still, even in this apparently simple feature we have a problem, for the average motor boat operator will persist in running his motor too cool for efficient results. The use of a temperature indicator is growing more common in motor boats, and this instrument, in connection with means of regulating the supply of water to the circulating system makes it possible to run a marine powerplant at the temperature where maximum efficiency is obtained—if the operator will do it. The effect of temperature upon motor efficiency is not yet fully appreciated in the marine field.

The growing use of the Diesel and the so-called semi-Diesel and surface ignition powerplants has brought a new set of problems for the marine engineer. Motors of this class are especially suitable for commercial installations and their development is linked with the growing appreciation of the importance of water transportation of freight.

An Aluminum-Copper Alloy

A NEW copper aluminum alloy known as Tsungani, which differs in physical characteristics from previous copper aluminum alloys in many respects, is being produced by the Alloys Motor Parts Mfg. Co. The manufacturers claim a tensile strength of over 21,000 lb. per sq. in., and a Brinell hardness of 80 to 90. The coefficient of expansion is .000008, much closer to that of cast iron than other aluminum alloys, according to the claims of the manufacturer. Piston clearances of .00055 to .00075 in. per inch of diameter of piston have given good results with this alloy, it is stated. Other claims are to the effect that the metal will not adhere or tear, even if the motor should be run dry or overheat, and that it will take a high polish in wearing. The material has been used for piston rings, for piston packing for steam engines, and also in air-cooled aviation engines. The pistons up as high as 7 in. in diameter have been manufactured from the material and it is claimed that there are now 700 cars in operation using the material.

Problems of the Front End Drive in Automobiles

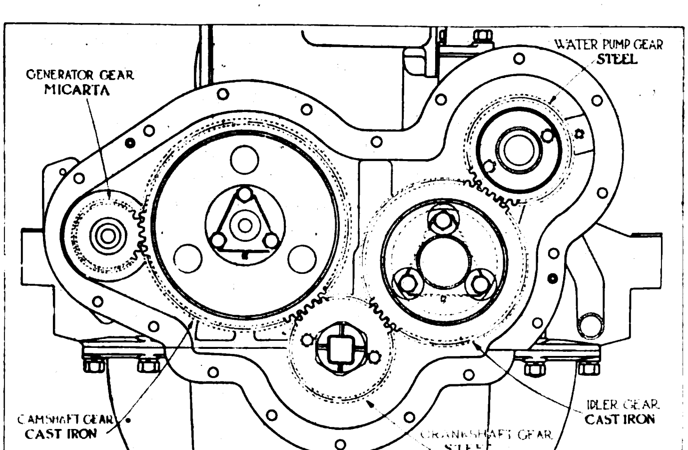
Problems of silence, accuracy of timing and frequency of replacement are presented to the engineer in connection with front end drives. Most stock engines are equipped with helical gears, but some are adaptable to chain gears as well. Present and future trends are discussed here.

By J. Edward Schipper

ENGINEERS whose high standing and long experience in the automotive industry entitle their opinions to respect, state that the front end drive of an automobile engine is still an unsolved problem; perfection has not been reached. The problem still presents difficulties and uncertainties which result in compromise designs to secure the best all-around results. This is not surprising when it is considered that some of the most difficult engineering problems must be solved in arriving at a design which will give the best satisfaction.

Silence, accuracy of timing, absence of replacement necessity, are the prime requisites in the front end drive, whether it be gear or chain, or a combination of the two, or some other method. Under these broad heads, however, there are some problems to be considered which involve the closest study of material and manufacture, as well as design as affected by the layout of the parts to be driven.

To make a brief survey of the situation as it stands to-day in passenger car practice, out of 125 models considered, 81 per cent have helical gear front end drives. Sixteen per cent have chain, 2 per cent spur and 1 per cent other means. Since half of these 125 models are assembled cars, however, this does not give an exactly accurate picture of the situation. Of the 60 models using engines manufactured by the car makers themselves, 20 models, or 33⅓ per cent, are using chain drive, and 40, or 66⅔ per cent, are using helical gears. This neglects the spur and worm gear which are employed on one or two models and which need not be considered in this study. The Ford car, of course, employs spur gears, this being a straight cost proposition, and while on a production basis it would appear as a considerable factor from a general engineering study, it need not be considered.



Layout of timing gears on Buda stock engine which employ steel gears for the crankshaft and water pump, cast iron for the idler gear and camshaft gear and Micarta for the generator gear.

The stock engines made by Continental, Lycoming, Herschell-Spillman and others are all equipped with helical gears. In other words, no assembled cars are using the chain front end drive at the present writing, because none of the stock engines are so put out. There are a few of the stock engines, however, which are being so arranged that the timing gear drive may be adapted either to chain or helical gears, and it is probable that within the next year or two some of the assembled cars will be using the silent chain in place of the helical gears.

In a great majority of instances, those using the helical drive employ alternating cast iron and steel gears. These work together with far less resonancy than steel against steel and at the same time the wearing qualities are apparently very desirable. This steel and iron layout at the present time outnumbers all other types of front end drive, and while the tendency is drifting toward the chain and toward compressed fabric gears, it still remains in the ascendancy on a percentage basis.

Forged Duralumin gears in place of cast iron are being used very successfully by the Continental Motors Co. and by Marmon. The advantages of Duralumin are its good bearing qualities, non-resonance, and particularly that the rate of expansion of the Duralumin gear is the same as that of the gearcase, and consequently, the center distances do not alter when the motor becomes warm. The Continental company states that this is a very appreciable factor in maintaining the silence of the front end drive. The characteristic property which distinguishes Duralumin from other aluminum alloys is that it can be forged. It can be hardened and materially strengthened by quenching from a high temperature, and its properties can be further improved by aging at room temperature.

Duralumin contains upward of 90 per cent. aluminum; 3 to 5 per cent copper; 0.4 to 1 per cent of magnesium and 0.4 to 1 per cent of manganese. It has a specific gravity of 2.8 as compared with 7.8 for steel. The alloy has good bearing properties, as shown by tests, where for shaft speeds exceeding 700 r.p.m. and loads exceeding 200 lb. per sq. in., the friction is less than with babbitt bearings. As regards resistance to fatigue, Duralumin is said to be superior to mild steels when stressed below its elastic limit. The timing gears are made from drop forged blanks. The fact that the pitch line contact of the gears is maintained works for silence, whether the engine is hot or cold, and where weight is a factor, there is, of course, a gain made by the use of this alloy. It is very probable that the use of Duralumin gears will increase.

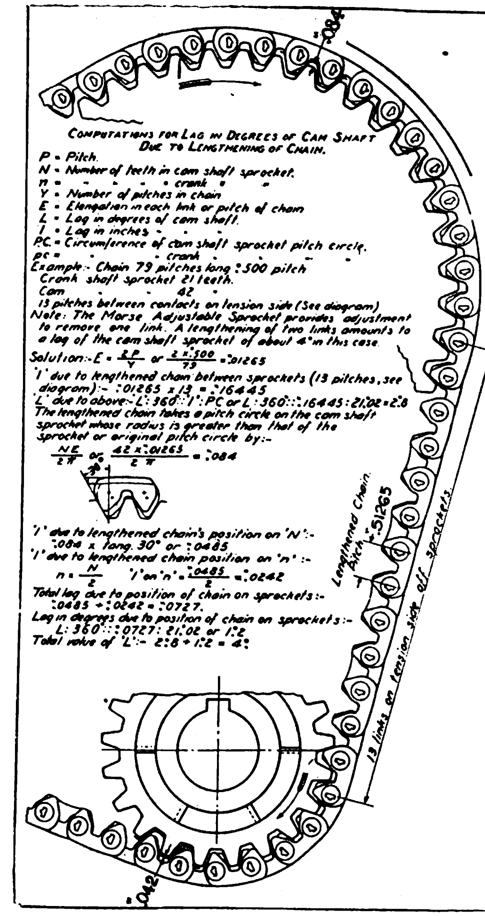
It is of interest to note that as a mark toward the tendency toward chain drive and toward the use of special material such as compressed cotton or Bakelite Micarta for the helical gear drive, the newer designed cars are using to a large extent either of these two methods. The LaFayette, Lincoln, new Packard single six, and the new Studebaker light six are all using silent chain drive. The 1921 Buick, Sheridan, Paige, C. H. Willis and DuPont cars are among the new designs using fabroil gears, which are a special compressed, spirally wound cotton type made by the General Electric Company.

So far as engineering opinion in the country goes, it is very apparent that matters stand about equally divided between the improved types of helical gear front end drive and chain front end drive for passenger car usage where silence is just as important a factor as long life. From a life standpoint, there is, of course, nothing to be said against the wide face spur or bevel type gear, and for truck practice it is very likely that this is going to remain practically universal. Demand for silence, however, introduces some factors which necessitate additional care.

In the consideration of chain front end drive, there are a number of matters to be given weight which experience during the past few years have shown to be of the highest importance, if economical maintenance is to be secured. There have been installations of chains which have proven expensive from the owner's standpoint. On one particular make of car, it was found necessary on early installations to recommend a replacement of the chain at the end of every 10,000 miles. This chain necessitated other work being done, which practically always ran the owner's bill to about $50.00. This expenditure of $50.00 every 10,000 miles means one-half cent per mile for chain maintenance, which is altogether out of proportion and not to be tolerated in any good design. If this proportion of expense of maintenance were to be multiplied by all the parts in the engine, the owner would find his upkeep bills far out of proportion to the service rendered. Happily, however, it has been found possible to materially reduce this by proper design considerations.

The Morse Chain Co., whose installations are used in several passenger cars, provides three nominal widths for the front end drive of high speed engines. These are, 1 in.; 1¼ in. and 1½ in., all ½ in. pitch. In the layout of the chain drive, either an even or odd number of teeth may be used in the sprockets, an odd number of links in the chain such as 51, 53, 55, etc., is required, however. The maximum number of teeth permissible in the crankshaft sprocket is dependent on the engine speed at the normal running speed of the car. In other words, the ratio in the rear axle and the diameter of the road wheels largely control the maximum number of teeth permissible in the crankshaft sprocket. On the ordinary car, it is undesirable to use more than 24 teeth in the crankshaft sprocket, which provides 1 ft. of chain speed per revolution per minute of the engine. For silence, it is undesirable to use fewer than 18 teeth in the crankshaft sprocket. This, of course, means 36 teeth in the camshaft sprocket to secure the half time. A driven sprocket is permissible with as few as 14 teeth, but not less. The recommendation of the Morse company is that all sprockets of less than 31 teeth should be made of low carbon steel; that is, from 10 per cent to 20 per cent carbon O. H. carbonized and hardened 1/32 in. deep. Sprockets of more than 30 teeth can be made of high carbon steel, heat treated, semi-steel casting, or of a very good grade of cast iron.

Another one of the fixed rules in connection with the Morse chain and generally applicable to all chain installations is that it is undesirable to drive any chain with less than 90 per cent chain contact on any of the driven



Layout of typical three-wheel, Morse silent chain drive, showing computation of camshaft lag due to lengthening of chain.

sprockets, and not less than 100 deg. contact on the driving sprockets.

The importance of proper adjustment means cannot be exaggerated in the installation of the chain drive. To secure the full efficiency of the chain and to reap the advantages, particularly as far as silence is concerned, some means of taking up the normal stretch must be provided. An accessible chain adjustment equal to one full link must be provided, and it must be remembered that this adjustment should be accessible or it will not be given the attention necessary. There are several forms of chain adjustments, the most suitable means depending upon the type of layout. For istance, on a triangular drive where the three points of the triangle are made up by the crankshaft, camshaft and generator sprocket, a very accessible and satisfactory adjustment may be provided by the use of the S. A. E. standard generator flange. This is shown in the S. A. E. handbook, Vol. 1, pages B-17 and B-18. Each flange mounting size is provided in this standard with a pilot for locating in a bored hole when used with a gear drive, and with slotted holes to allow for adjustments when used with chain drive. In the latter case, the hole in the gearcase should clear the pilot.

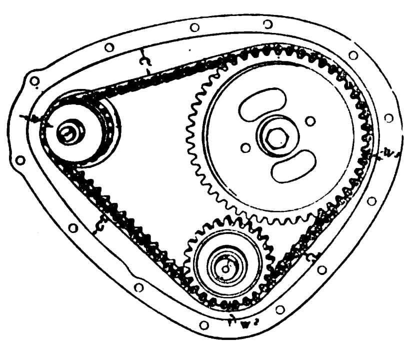
When the triangular drive is used with fixed shaft centers, the Morse Chain Co. provides an adjustable sprocket which has been used successfully on the Packard, Winton, Haynes, Jeffery and other cars. This adjustable sprocket is illustrated and will be described in detail hereafter. Other chain companies have adjustment features which will be described below.

In designing the adjustment, the amount provided should be such that the slack taken up in the chain is equal to a full link plus 10 per cent, or .55 in. A caution which is given in connection with idlers is not to use an idler sprocket for taking up chain slack unless the idler is designed to consume sufficient power to prevent the idler from playing in the chain, as a free idler sprocket

in the front end of an engine is bound to cause a marbly noise.

The Morse adjustable sprocket, which is illustrated on page 1299, is designed to facilitate adjustments of the chain on engines where it is not possible to move one of the shafts. Referring to the illustration, it will be noted that the sprocket, instead of being mounted on the shaft, is mounted on a bearing which is eccentric to the shaft. The chain rotating the sprocket rotates the shaft by means of a connecting universal coupling of the Oldham type. The bearing on which the sprocket is carried is mounted in the case, concentric with the shaft, and by rotating the bearing, the sprocket is moved, thus adjusting the chain. This type of adjustment is applicable to any type of drive.

A question which frequently arises in the minds of engineers is the amount of clearance to allow between the back of the chain and the gearcase. In laying out clearance, the minimum below the crankshaft gear and above the camshaft gear on a triangular layout should be the pitch plus 1/8 in., or since 1/2 in. pitch is universal, 5/8 in. clearance is desirable. Where there is an adjustment, the clearance between the back of the chain and the case at the generator or adjustable sprocket should be



Typical three-wheel Morse silent chain drive showing recommended case clearance.

P = Pitch of chain or 1/2 in.

Wheel (front top of tooth)
$W^1 = P + 1/8$ in. + Adjustment = 15/16 in.
$W^2 = P + 1/8$ in. + 5/8 in.
$W^3 = P + 1/8$ in. + 5/8 in.

Chain (from top of chain)
$C^1 = P \times 2\frac{1}{2}$ in. = $1\frac{1}{4}$ in.
$C^2 = P \times 3$ in. = $1\frac{1}{2}$ in.
$C^3 = P \times 2 = 1$ in.

Note—C^1, C^2 and C^3 entirely depends on the length of strand.

1/8 in. plus the pitch plus the adjustment, or 15/16 of an inch at this point.

On two sprocket drives where the driven sprocket runs two or more times the crankshaft speeds, and the centers are of a certain distance which depends on the balance of the motor, the chain is liable to have a whip which tends to shorten its life considerably, and, in fact, to increase vibration throughout the entire engine. This whip is due to a synchronized vibration originating in the engine and picked up by the chain, when the speed, weight and length of the chain become synchronized with motor vibration. A compensating sprocket can be used to break up this vibration and prevent the whip.

Unless adjustments as outlined are provided, the chain will eventually jump the teeth of the crankshaft sprocket, due to the gradual lengthening which occurs, because of the slight wear in the joints. Where the design of the chain is such that gravity tends to draw both fans of the chain away from the crankshaft sprockets and the contact is less than 130 deg., the chain is apt to jump and throw the engine out of time. Shoes on the case are provided in some installations to cause noise when the chain becomes loose enough to be apt to jump. This warns the operator and makes him adjust the chain and take up the slack before it can jump from the sprocket.

The layout of sprocket centers is, of course, of primary importance in designing a chain drive. In designing triangular layouts on new engines, it is highly desirable that a chain specialist be consulted before a center distance is adopted, and engineers should consult with the chain makers and allow their engineering departments to assist on the original layout, in order to secure the best results.

Installations of the Link Belt chain show some particularly interesting features of front end drive practice. One of the features in connection with some of the Link Belt installations is the highly successful use of the automatic idler as employed on the Mercer and Brewster cars. The feature of the automatic idler for taking up wear in chains as used on the engine is not new, but heretofore has proven unsuccessful because there was a certain point in the speed of an engine where the automatic idler had a tendency to vibrate excessively, causing considerable noise. The automatic idler, as arranged by the Link Belt Co., is claimed to absolutely be free from vibration at any speeds.

The Link Belt Company has recently placed on the market a new type of front end drive chain, which has taken about 10 yr. to develop. This chain is known as the unit chain, because in it the liner type of bushings used in all previous types of Link Belt silent chains have been eliminated. This has also eliminated two points of wear at each articulation. Another feature of the chain is that it presents practically a solid contact with the tooth of the wheel on which it travels, and thus allows oil to form a silencing pad between the tooth of the wheel and the chain. It is claimed that, regardless of the speed, this chain produces merely a very dull, metallic click, which totally disappears when the chain is encased.

Another feature of this particular chain is the spacing of the links. The spacing is determined by integral parts of the link, and it is impossible for any particular joint to be tight. Tests on the final form of this chain have been carried on for practically two years, and several chains are said to have run for a distance equal to 48,000 to 50,000 miles in engines, yet the stretch is under 0.02 in.

The outstanding factor of the Whitney silent chain is the special cylindrical joint designed to insure long wear. It is claimed that the joint wearing area is a more important feature than the tensile strength of the chain, as the factor of safety is so high that the breaking of chains in service is very rare.

The joint of the Whitney chain is shown in the illustrations herewith. Short, hardened steel bushings are used, which fit tightly at each end into regular toothed, inside links, while the two toothed links in the center turn freely on the bushing. The links which fit the bushings tightly are designated "tight hole links" and are forced on the bushings under very heavy pressure. The two center links which turn on the bushings are designated "loose hole links." A length of chain comprising these two styles of links assembled with the bushings is designated a "B" unit. For the smaller pitches, the separate links are 1/16 in. thick, so that each unit is 1/4 in. wide. These units are placed side by side to make up the desired width of chain. Hardened nickel steel rivets of the proper length secured at one end to outside links are passed through the bushings into another outside link and riveted in place. This construction, it will be seen, gives for each joint four bearing surfaces made up entirely of hardened steel, and it is upon this joint construction that the claims for the wearing qualities of the chain are made.

Two general styles of Whitney chains are at present on the market. One is the side guide type, which has guide plates along each edge of the chain. In this construction, the outside unit, designated as "A" unit, is made up of one tight-hole guide plate and one tight-hole inside link fitting the bushing tightly, with a loose-hole link turning on the bushing between them. This makes a unit 3/16 in. wide, 1/8 of which is on the sprocket teeth, while 1/16 in., the guide plate, is outside the sprocket.

The other style of Whitney chain has a single guide plate in the center which runs in a groove provided in the sprocket. In this case also a special unit is used, so constructed that any desired width may be obtained by combining it with the proper number of regular "B" units.

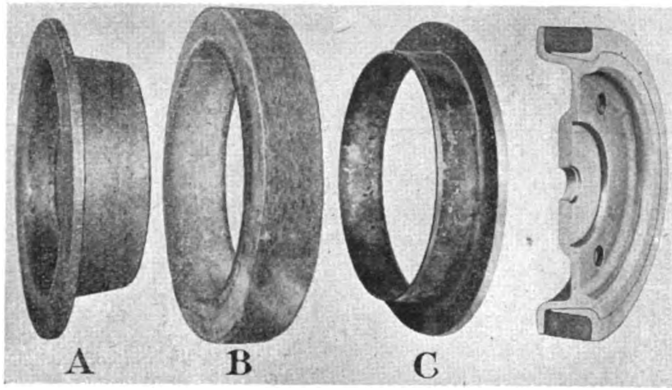
(6) Typical Morse triangular drive applied to four and six-cylinder engines with the cam and accessory shaft on the right side.
(7) Morse single adjustment usually applied to accessory shaft and essential where the shaft contains two or more units and cannot be moved to take up chain slack.
(8) Morse double adjustment adapted to eight-cylinder engines containing two loops of chain. The adjustment is applied to the camshaft.
(9) Link Belt silent chain drive in the front end of a Mercer engine with automatic idler adjustment. The idler wheel runs loose on an eccentric bushing with an internal adjustment spring.
(10) Link Belt installation on Brewster, driving camshaft, fan shaft, and auxiliary shaft, with idler adjustment on back.
(11) Whitney chain front end drive on eight cylinder engine, showing chain drive to camshaft and generator shaft.

The center guide style of silent chain in the ½ in. pitch has been most commonly adapted for use in front end drives. The links are made of alloy steel, heat treated. The holes in each link are reamed to size and the faces of the links where they engage the sprocket teeth are milled to a smooth surface located accurately with reference to the holes.

The type of chain used for the front drive does not materially affect the spacing of the sprockets and the layout of the auxiliary drives such as generator, water pump,



Parts of Fabroil automobile gear. A. Drop forged hub. B. Cotton filler. Drop forged shroud at C. Sectional view of gear.

magneto, timer, distributor, etc. The same rules regarding adjusting devices and selection of center distances apply. One of the main requirements is proper lubrication, and whatever the lubricating system in use, an oil lead should be provided to deliver a constant stream of oil to the inside of the chain. A vent or breather should also be provided at the highest point of the chain case, unless the highest part of the chain case has an opening to the main crankcase which is provided with a liberal vent. The sprockets should be cut with cutters and hobs approved by the chain company which is to provide the chains, as otherwise unsatisfactory operation may result.

A recent investigation of the causes of rapid chain wear in certain parts of the country brought to light some interesting facts. For instance, it was found that in Birmingham, Ala., the life of the chain was noticeably shorter than in other parts of the country. Investigation disclosed a tendency for the etching of the pins. This was found to be due to sulphuric acid in the oil, and in tracing it back it was found that this came from the use of benzol in the fuel. It is believed that when the sulphuric acid content in the crankcase oil is equal to 0.02 per cent., galvanic action takes place and etching of the chain occurs while the car is standing still. A teaspoonful of slack lime in the crankcase would, of course, neutralize the oil, but this is not good for the engine bearings.

Gears of compressed cotton or fabric cut with helical teeth have excited the interest of engineers for several years. There are hundreds of thousands of these gears in use, and they are proving very satisfactory in practically

all installations. The working portion of the Fabroil gear, which is the trade name of the compressed cotton gear sold by the General Electric Co., is cotton, which is held highly compressed between steel shrouds or end plates. The cotton receives a vacuum-oil treatment, which acts as an initial lubrication. These gears have been in use now for over eight years, and about twenty manufacturers of passenger automobiles are now using them. They are generally furnished in the form of gear blanks, finished ready for tooth cutting. The Fabroil gear is generally used as a camshaft or an idler gear and the sizes specified by different users are contained in the tabulation herewith.

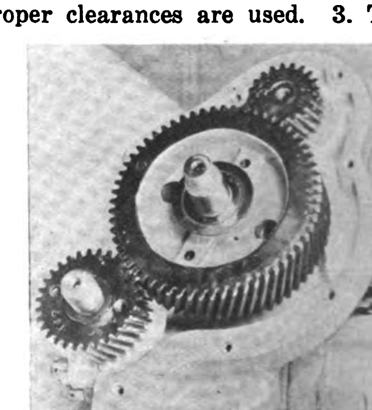
Steel forgings used in the construction of Fabroil timing gears are made of L section in order to provide the strength necessary to hold the cotton portion in compression. By a series of operations the fibres of the cotton are made to assume positions closely paralleling the outline of the tooth profiles, alternate layers crossing to parallel opposite profiles. This produces a triangular bridge truss structure, developing the maximum strength and wear resistance without sacrifice of elasticity.

Generally, the teeth of the timing gear train are cut spirally, and experience has shown that a spiral angle of about 20 deg. will give smooth operation with only moderate end thrust. With a large spiral angle the Fabroil gear would be greatly weakened, but the 20 deg. spiral angle is said to be well within safe limits. A Fabroil idler or camshaft gear works well against the steel crankshaft gear, and this combination has been approved by a great many engineers for passenger car use. The latest series of Buick, in which a special endeavor was made to quiet the timing gears, employs Fabroil gears. On a test made on a Buick six-cylinder 1920 model, with the motor run at constant speed of 1220 r.p.m., or 25.24 miles per hr., a wear of only 0.002 in. was found in 30,000 miles of running. The gears are cut with 10.240 pitch teeth having a 20 deg. spiral angle, the Fabroil face being 1¼ in., and the metal face 1⅛ in. The gears are lubricated by drilling a ½ in. hole in the wall above the shelf used to retain oil for lubricating the camshaft bearing.

Lubrication of the front end drive, whether chain or timing gear, has been given a great amount of attention by engineers. On the National car, the chain is continuously oiled by a small stream of oil, a great deal of oil being thrown on it when the pressure regulator in the oiling system opens, which it does at about 10 lb. pressure. This means that after the car gets up to a speed of about 15 miles per hour the entire front of the chain housing is flooded with oil. The National company uses a Morse chain of 1½ in. width.

On Peerless cars a gear front end drive has been used for a great many years. For several years the Peerless company has used a Fabroil camshaft gear, for the following reasons:

"1. It is the simplest construction known. 2. The use of the spiral gear to a large extent eliminates gear noise. However, with the combined use of the spiral tooth and Fabroil gear, noise is practically eliminated if the gear is properly cut and proper clearances are used. 3. The



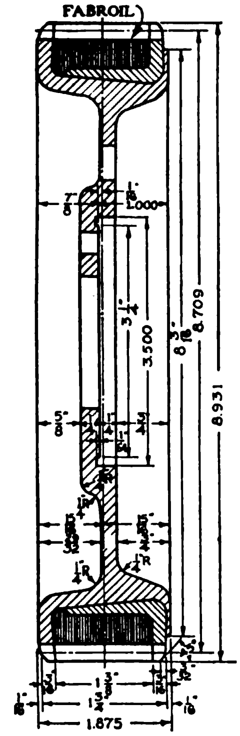
Fabroil timing gears employed on Buick 1921 car.

gears are certain to give correct timing and not to jump a tooth occasionally, as may happen with other methods. 4. No adjustments are necessary. 5. Vibrations which occur at critical speeds do not show themselves in the way of noise or hammer. Furthermore, there is no crit-

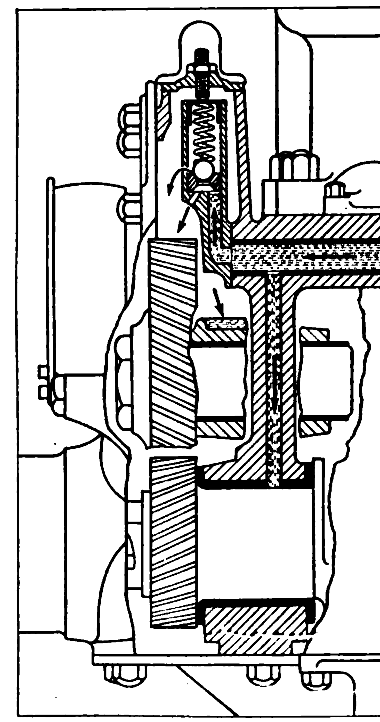
ical speed in the gears at which they may vibrate. 6. While fitting of the gears requires close work in the factory and entails careful attention, the job when passed is good for thousands of miles without any expenditure for adjustment or upkeep."

The Apperson company uses a cast iron gear on the camshaft and a drop forged steel gear on the crankshaft. The pitch diameter of these gears is 6¾ and 3⅜ in. The teeth are cut with a ten pitch cutter. The angle of spiral is 27 deg. 16 min. The normal circular pitch is 0.3141 and the lead is 41.144 in. right hand spiral. The Apperson installation mentioned employs only two gears in the gear train, the crankshaft pinion and the camshaft gear vertically above it, as this is an eight-cylinder engine. On truck engines, this practice of using steel against iron is practically universal. There noise is not such a factor and is a secondary consideration to life. In passenger car practice, silent operation is most essential and for this reason another factor enters the problems, namely, resonance of the timing gearcase.

The search for non-resonant materials for timing gearcases has not developed anything which is very much superior to cast iron. Aluminum, when properly ribbed, is not bad. Most engineers, however, agree that cast iron is superior from a resonance standpoint, even though heavier. The use of the solid web in the idler gear in place of spokes has also been found to reduce sound to some extent. Sources of vibration, however, cannot always be foreseen, and sample engines often show too much resonance in the timing gear train and gearcase in spite of precautions taken to guard against this trouble. Practically all designers have had some experience with unexpected noises developing at this point, and many amusing stories are told of the tuning fork effect of certain types of timing gearcase covers. With practically all other noises in the engine almost completely subdued this timing gear problem is assuming great interest to all engineers concerned in the development of quiet engines.



The Peerless camshaft gear is of Fabroil with a steel hub.



Method of lubricating timing gears on Continental engine. In addition to the oil leads to the timing gears, excess oil from the overflow passes back to the crankcase over the faces of the timing gears, so that at higher speeds they are copiously lubricated.

Problems and Possibilities of the Aluminum Piston

(*Continued from page* 1266)

become somewhat loose when the piston is hot, owing to the higher expansion of the aluminum as compared with the iron or steel bush. If the fit becomes too loose, then "hammering" and consequent wear is likely to result. From this point of view, the "cast in" bush is to be preferred. Here the "fit" is between hot aluminum and comparatively cold iron, and subsequent shrinkage leaves the light alloy casting under an internal tensile stress around the bush. This must not be permitted to become unduly high, otherwise the casting may crack. So long as this is avoided, however, the presence of such a stress is a desirable feature, since the heating of the piston then merely releases the stress and still leaves the bush tight in its place. Allowing the piston pin simply to "float" directly in a simple hole machined in a boss of the aluminum alloy casting has also been tried, but it is doubtful whether the bearing surface thus obtained is large enough. There is some reason to think that aluminum alloys afford a good bearing surface for moving steel parts, but it is necessary that the working pressure should be kept very low. If the piston pin were large enough—or were given an increased diameter at the ends, therefore, the simple "direct" construction would probably prove quite satisfactory.

Although it cannot be claimed that the whole subject of the aluminum alloy piston has been exhaustively treated in what has here been said, it is hoped that the leading points have been dealt with to a sufficient extent to enable those designers and constructors interested in the matter to follow it up further and to form their own opinions. Whether the aluminum alloy piston has "come to stay" in the automobile engine is still a matter for personal opinion. That it does allow of the construction of an engine of higher efficiency cannot be doubted, and since reduction of weight in the automobile necessarily implies the use of a more efficient power unit, there is some reason to think that on this ground there is an important future for the light alloy piston. Some advanced thinkers regard it as being but the first step to an "all aluminum" engine or even an "all aluminum automobile," and there can be no doubt that both cylinder castings and connecting rod forgings of light alloys have been successfully used. It will be well, therefore, for progressive automobile designers and engineers to bear the future possibilities of light alloys very carefully in mind.

THE situation of the petroleum industry in Rumania is reported to be such that its prosperity is greatly endangered. For a long time the majority of the wells have been exploited with the aid of foreign capital. This exploitation has practically been put to an end by the refusal of the Rumanian Government to permit the exportation of the petroleum except for domestic needs. Moreover, by a recent decree the Government is trying to create a monopoly of the transport of petroleum, with the object of later transferring this monopoly to a private corporation. It is evident that under these conditions foreign capital will not be interested in further development of these oil fields.

American and British Practice in Clutch Design

A paper in which the advantages and disadvantages of various types of clutches are discussed and the merits and demerits of many design features are pointed out. Notes on the theory of design and a tabulation of dimensions, pressures, capacity, etc., of many makes are also given.

By Herbert Chase[1]

THE objects of this paper are to (*a*) set down in convenient form for reference purposes particulars concerning American and British[2] practice in clutch design, (*b*) compare the advantages and disadvantages of various types of clutches and (*c*) give some notes on the theory of design without attempting a comprehensive treatment of the numerous factors involved in this theory. The descriptive portion deals almost entirely with clutches used on passenger cars and trucks, but some of the clutches described are applicable to other automotive uses. The notes on the theory of design apply in general to all automotive clutches. The clutches considered can be divided into the four general classes of cone, single plate, multiple disk and shoe or band types.

The Cone Type

The cone type was used almost exclusively for many years for both passenger cars and trucks. It still is used very widely by Continental European and British builders, and has a considerable number of advocates in this country. It is simple in construction and can be made light enough to be brought quickly to rest when changing gear, at least in moderate capacities. In certain forms it is not expensive to manufacture and is fairly reliable; but, for a variety of reasons, it has steadily lost ground in this country and is used to-day by less than 8 per cent of car and 6 per cent of truck builders. In England over 60 per cent of car chassis and nearly 80 per cent of truck chassis still have cone clutches. It should be borne in mind that nearly all British builders make their own clutches, and that the average torque transmitted is much lower than it is in this country because British engines are smaller and, in the average case, of rather higher speed than American engines. Preference for the cone type in Europe is ascribed by some to simplicity and lower cost of production when the quantity is small. There are some who say that the cone type is ideal when properly constructed, and one British writer[3] contends that if the same ingenuity had been expended on the cone type as on the plate and disk types the first named would have proved so cheap, simple and satisfactory that other types would be considered expensive luxuries.

The chief failing of the cone type has perhaps been due to the fact that, as frequently constructed, the full pressure of the spring comes into action immediately upon engagement of the friction surface, thus causing the clutch to grab or pick up its load suddenly. To some extent at least this can be avoided by a variety of means. Among the simplest of these is the placing of subsidiary springs under the facing, so that the whole of the facing is not engaged simultaneously. A dashpot, similar to that shown in Fig. 1, also can be used, but this precludes sudden engagement which is sometimes necessary. Another expedient is to arrange two or more springs so that they come progressively into action on the cone during the period of engagement. Practice in respect to the angle of the cone varies widely, from 10 to 16 deg. in British types. The sharper the angle used, the lighter is the spring pressure required to carry a given load with a given diameter and nature of surface. The clutch is likely to grab when the angle is made too fine, while a fairly wide angle tends to prevent grabbing but requires a heavy spring. The advantages of both are said to be realized in the construction shown in Fig. 2, in which a double cone

[1]This paper, prepared originally for exclusive use in the Engineering Number of AUTOMOTIVE INDUSTRIES, was accepted for and presented at the Semi-Annual Meeting of the Society of Automotive Engineers. A few slight revisions have been made in the text and table presented in printed form at the meeting.

[2]The data and most of the particulars regarding British clutch practice were furnished by M. W. Bourdon, to whom acknowledgment is hereby made.

[3]See a paper entitled Developments in Transmission by Capt. S. Bramley-Moore presented before the Institution of Automobile Engineers and published in the Journal of the Society of Automotive Engineers for April, 1921.

is employed. The wide angle surface engages first, while the narrow angle face coming later into engagement furnishes sufficient friction to carry the full load without slip.

Not many years ago all cone clutch facings were made of leather, which often becomes hard and sometimes glazed due to slipping on engagement. The clutch then either fails to carry the load or grabs until the facing is treated with oil. Too much oil lowers the friction coefficient enough to bring about slipping and fullers' earth must then be applied to prevent slipping. Annoyance of this kind caused prejudice against the cone type and has favored the development of other types. To-day, asbestos fabric is employed frequently for cone, as well as for other clutch facings. Cone clutches are sometimes allowed to run in oil, as in the case of the Humber clutch shown in Fig. 3. This keeps the facing material, which is leather in this case, relatively soft and pliable but of course decreases the friction coefficient and, other things being equal, requires the use of a stronger spring.

To facilitate gear changing, it is desirable to decrease the moment of inertia of the driven member attached to the transmission; hence, its weight and diameter should be kept as low as possible. Some consider American practice superior to the British in this respect and say that gear changing is easier on the American cars, but this may be due partly to other factors. To minimize weight, either pressed steel or aluminum is employed for cone clutches. In some cases, as in the Clement-Talbot clutch shown in Fig. 4, the friction facing is attached to the female driving member instead of to the driven member, and the driven member is thus further lightened. This practice is said to have not been universally successful, due to difficulty in attaching the facing satisfactorily. In some cases facings are made and secured in segments, rather than in one piece, when they are carried by the driving member. The builder of the British Phoenix cars has followed the practice for many years of using an aluminum cone running in oil and bearing directly on the cast iron flywheel. Phoenix cars are of small size, but the practice has apparently been successful, for it is followed even in the latest and largest 18-hp. model of this maker.

Not all cones are of the conventional form, fitting directly into the flywheel. Some are of the so-called inverted type, such as the Humber, shown in Fig. 3, and are pushed forward toward the flywheel to disengage them. In this case a separate ring is required between the clutch and the flywheel proper. Nothing appears to be gained over the conventional type, unless it be in the compactness realized by placing the spring between the flywheel and the clutch. Nearly all springs used in clutch construction are either helical or volute types under compression. In many cases a single heavy spring centrally located is used, but two or more, equally spaced around the circumference near the periphery of the clutch are often employed. An exception is the Thornycroft clutch illustrated in Fig. 5, which employs two laminated leaf springs, one on each side of the axis. These are fastened to the flywheel rim at each end by bolts, and make contact at the center with the ball thrust bearing. The thrust of the engaging spring is usually taken by the flywheel clutch unit; that is, the two or sometimes the clutch alone are self-contained, and no thrust is transmitted to external members except on disengagement. This is not true, however, in the case of the Daimler car, which has an exterior spring attached to the chassis frame applying pressure to the clutch and flywheel which must be taken up on the crankshaft. This construction is, of course, very much out of date.

So far as British practice is concerned, it appears that there is not much to choose between well made cone and plate types. Their respective merits are so nearly the same that even experienced users accept either type without question. In other words, the type of clutch used is not a selling point in England. This can hardly be said to apply in this country, where perhaps the cone type has not been developed to the same extent as in British practice. The unsatisfactory performance of the cone type in some instances, and other factors, have led to the development of other types here, notably the multiple disk type, which has advanced further and is more widely used in this country than in Great Britain or Continental Europe.

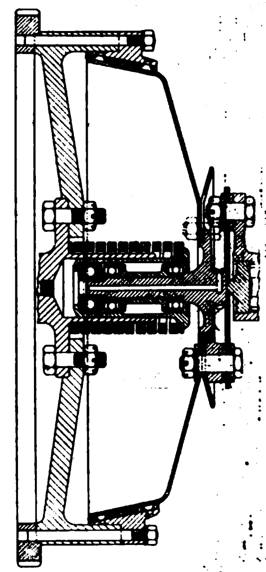

Fig. 4—The Clement-Talbot clutch.

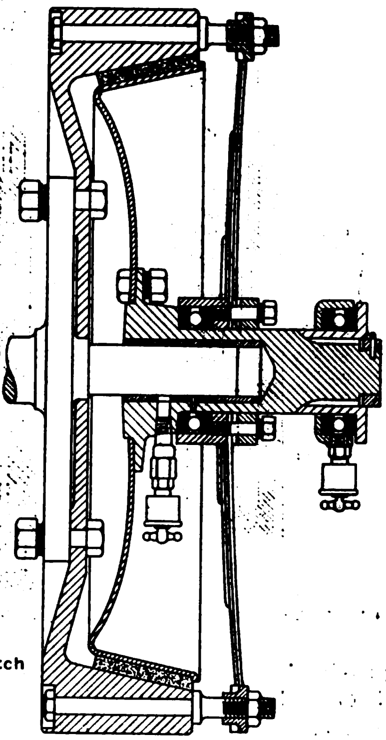

Fig. 5—The Thornycroft clutch

The Single Plate Type

The single plate type of clutch is used widely in both this country and Europe. When well made and properly adjusted, it is smooth acting. It is of simple construction and can be made with few parts; consequently it lends itself to economical production in quantity. As compared with the cone and the multiple disk types, heavier spring pressure is required to carry the same torque; hence, if the same linkage is used, the pedal pressure necessary to disengage the clutch is greater, unless a much larger diameter of plate is employed. For this reason multiplying levers are employed in the throwout mechanism, and many different arrangements of levers are used in plate clutches of different makes. In some cases the levers are attached to and rotate with the driving member, while in others external leverage, aside from that on the pedal lever, is employed.

Figs. 6 to 13 show plate clutches using multiplying throw-out levers. Some of these are employed on trucks and some in passenger car service. A somewhat different design of lever is employed in all of these eight clutches. In the case of the Autocar, Fig. 6, the Dennis, Fig. 7, and the Napier, Fig. 8, adjusting screws which can be backed off as the facings wear are provided on the levers. The Bristol, Fig. 9, the Halley, Fig. 10, the Mack, Fig. 11, and the Austin, Fig. 12, appear to have no provision for adjustment within the clutch itself. On the Arrol Johnston, Fig. 13, the spring pressure can be varied by turning the threaded spring caps, but the levers are non-adjustable. In all of these eight clutches three or more springs, equally spaced in a circle having a radius

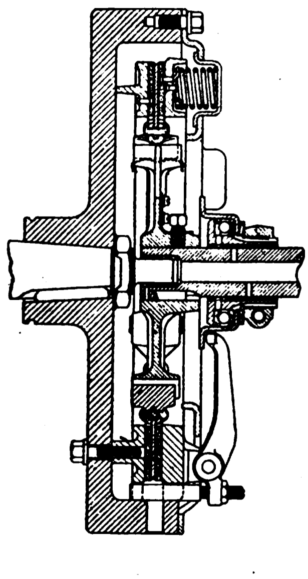

Fig. 6—The Autocar clutch.

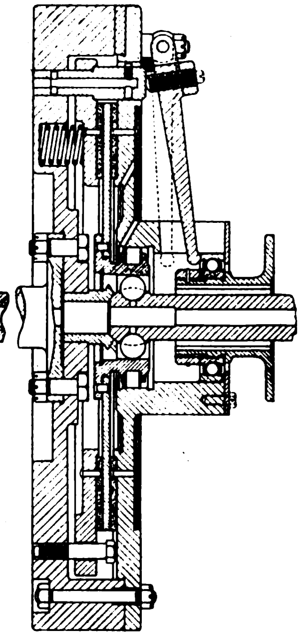

Fig. 7—The Dennis 2-ton clutch

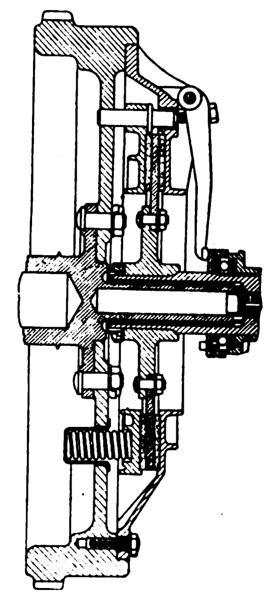

Fig. 8—The 40 to 50-hp. Napier clutch.

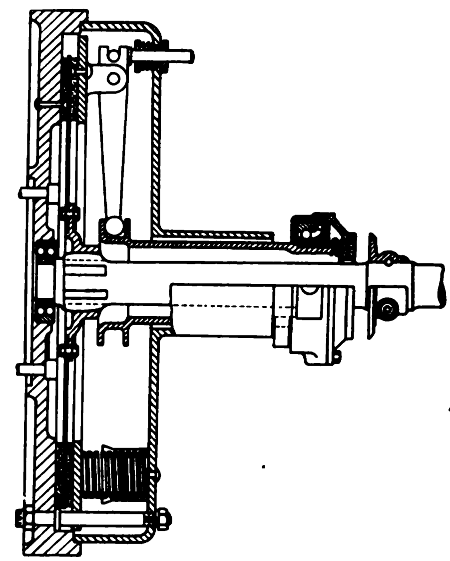

Fig. 9—The Bristol 4-ton clutch

approximately equal to the mean radius of the friction disk or disks, are employed. These are so-called "direct acting springs," since their pressure acts directly upon the friction surfaces and not through levers, as in the types that will be described later. As the facings wear, the springs become somewhat longer and their pressure decreases correspondingly, but the increase in the length is usually small and, if the spring is properly proportioned, the decreased pressure is still within the capacity factor of safety allowed.

With the single plate type, the unit pressure on the friction surface usually is high and, since the slip with its consequent abrasive action which takes place during engagement and disengagement occurs as a rule only on two faces, the wear on these surfaces is relatively rapid. This disadvantage of the single plate type is minimized by making the disk of as large an area, and consequently as large in diameter, as is feasible; but, when the diameter is large, the inertia of the driven member becomes great and gear changing more difficult. To minimize the weight and inertia of the driven disk, it usually is made fairly thin and the friction surfaces are, as a rule, carried on the driving members. The thin plate is noticeable especially on the Bristol clutch shown in Fig. 9. In some cases, however, so thin a section has been employed that the heat caused by slipping has resulted in warping the plate enough to require its renewal. High temperatures are often reached when, as in traffic driving, slipping occurs frequently. Heat can radiate but slowly from plates so fully enclosed.

The Mack clutch illustrated in Fig. 11 is designed so that the driven friction disk only is clamped between the two driving members. It is carried by a light steel plate, but is riveted to this plate at points nearer to the center than the bearing surface. This arrangement, no doubt, adds somewhat to the moment of inertia, but it has the advantage of requiring only a single disk of friction material which takes the wear on both sides. Furthermore,

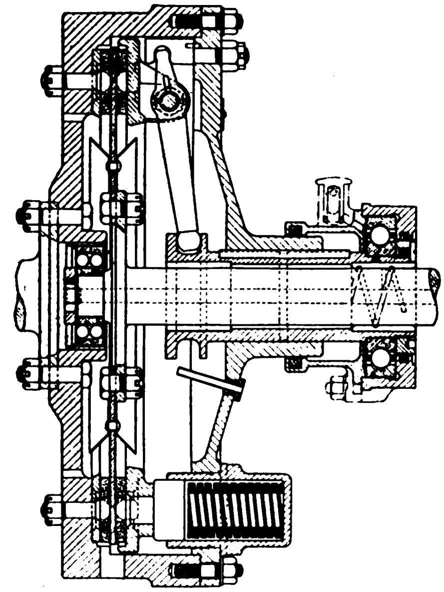

Fig. 10—The Halley 3½-ton clutch

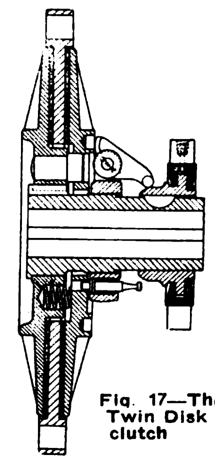

Fig. 17—The Twin Disk clutch

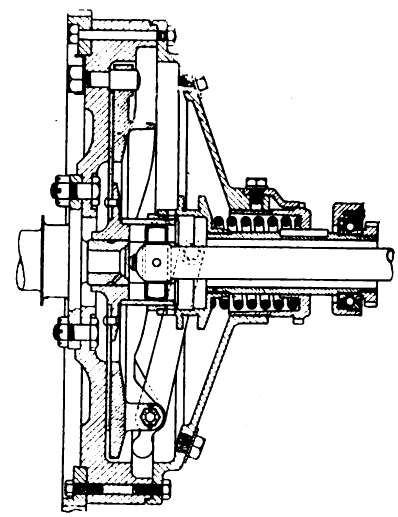

Fig. 16—The Rover clutch.

as wear occurs, the rivet heads never bear on the metallic friction surface as in most other constructions after considerable wear takes place. In this way the useful life of the friction disk is much increased. A somewhat different type of single plate clutch widely used in this country is shown in Figs. 14 to 16. This type employs a single spring placed co-axially with the clutch itself and arranged so that the pressure of the spring on the facings is multiplied by lever and toggle devices. The advocates of this type claim the advantage of uniform pressure at all points on the friction surface, which, they contend, is not secured when separate direct acting springs are employed. This advantage is, however, dependent upon having the same size and fit on the various bearing parts involved, as well as on equal wear; hence, there is some question whether a more uniform pressure is obtained in reality than is secured by properly calibrated sets of springs acting directly on the friction faces. One disadvantage resulting from the use of levers to multiply spring pressure is the fact that the motion of the long end of the lever due to wear on the facings is multiplied in the ratio of the lever arms. If this ratio be 5 to 1, wear of 1/16 in. on the facings means a 5/16-in. extension of the spring. In some designs this amount of motion will involve sufficient reduction of pressure to permit slipping and, since a motion of the throw-out sleeve of about ½ in. is usually allowed, it is necessary with this type to adjust with relative frequency. Hence, clutches of this type are, as a rule, provided with means for quick adjustment.

In the Borg & Beck clutch shown in Fig. 14 adjustment is made by turning the ring on which the toggle levers are carried, thus causing the inner ends of the toggles to bear sooner on the helical surfaces provided on the thrust ring. The toggle ring is then locked in place by two cap screws passing through the cover plate. In the Hoosier clutch, illustrated in Fig. 15, a similar adjustment is made by turning the threaded adjusting ring, which is then locked by cap screws in a manner similar to that used in the Borg & Beck clutch. The release sleeves used in these two clutches are attached to and turn with the driven member, while the collars against which the toggle levers bear at their inner ends turn with the driving member. This necessitates the use of an extra bearing between the two, which is not required in most other constructions. The facings in these two clutches are allowed to float; that is, they are not attached to either the driving or the driven members. Since no rivets are required, the facings can be used without renewal until nearly worn through.

The earlier types of multiple disc clutch ran in oil and used alternate disks of bronze and steel. With the exception of the Phoenix cars which, as stated above, use aluminum cone clutches running in oil and bearing on the cast iron flywheel, few other metal-to-metal clutches are used to-day. One of these is the Rover, shown in Fig. 16, which has a single phosphor bronze plate running in oil between two cast iron surfaces. Levers which multiply spring pressure on the friction surface are employed as in the case of the last two clutches mentioned, but these are not of the toggle type in which a certain wedging action occurs. The use of oil, of course, reduces the coefficient of friction, and this necessitates greater pressure than would be required otherwise. Other disadvantages encountered when disk or plate type clutches run in oil are cited under the head of multiple disk clutches. In the case of the Rover clutch the torque transmitted is only that of an engine of 12-hp. rating; hence, it would seem to be possible in a clutch of the proportions shown to work with a large factor of safety, and this is no doubt the case, for the clutch is said to work very well in practice. The Rover clutch is designed for use with a separate transmission; hence a universal joint is employed at its center. The disengaging sleeve is keyed to the driving member and therefore rotates with it. Through this sleeve passes the shaft of the universal joint which, of course, turns with the driven member; but, since this shaft does not touch the sleeve, no bearing is required between them and the thrust of the spring is taken against the casing direct. This makes the extra bearing used in the Borg & Beck and the Hoosier types unnecessary. Spring pressure can be varied by turning the threaded sleeve, against which it

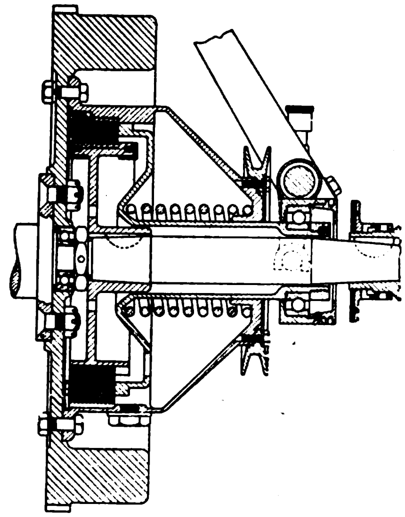

Fig. 18—The Vauxhall clutch

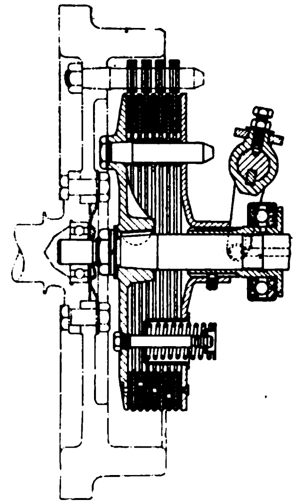

Fig. 19—The Hupmobile clutch.

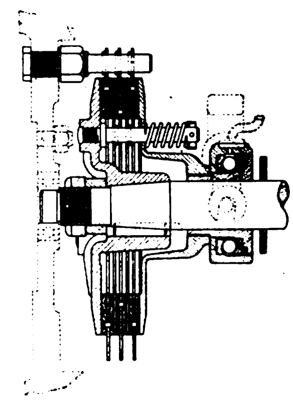

Fig. 20—The Detlaff clutch

bears, in or out of the conical housing. The bronze driven member apparently wears so little that no other adjustment is required.

A variation of what is essentially a single disk type of clutch is shown in Fig. 17. This is known as the Twin Disk clutch and has a pair of driven but only one driving plate, thus reversing the usual single plate arrangement and materially increasing the weight and inertia of the driven member. No engaging springs are used in the clutch. It is of the locking toggle type and consequently must be positively engaged and disengaged. For this reason it is not suited to or intended for use on automobiles or trucks, but can be used in some tractor applications. It is adjusted easily by disengaging the spring retained pin projecting from the threaded toggle carrier ring, and then turning this ring until the pin falls into another hole on the driven member.

The Multiple Disk Type

The multiple disk clutch is regarded by many American engineers as the best of all types for both passenger car and truck service, as is evidenced by the fact that it is used on nearly all of the more expensive cars produced here. This type of clutch has apparently been developed to a higher degree here than in Europe, while these other types, as previously pointed out, have seen the greater development. Partly for this reason, the multiple disk type is not used widely either in Great Britain or in Continental Europe, although some car builders there use it with evident satisfaction. The multiple disk type of clutch in most forms is more expensive to manufacture than other types, hence, its use has been more general in the higher priced cars. It is used, however, in many low or moderate priced cars, in the Ford and the Dodge cars for example, and is not inherently expensive to produce.

The earlier types of multiple disk clutch were of the metal-to-metal variety and used either all hardened steel disks or alternate disks of steel and bronze, or steel and copper. Some clutches of this type are still used, such as the Vauxhall, which is shown in Fig. 18. With this construction it is necessary for the clutch to run in oil. This permits a smooth engagement but the use of oil results in more or less trouble, for satisfactory operation of this variety of multiple disk clutch depends upon having both the correct viscosity and the proper quantity of lubricant. Too much or too viscous lubricant will tend to prevent proper engagement and consequently cause slipping, and will tend also to make adjoining disks adhere when disengagement is required, thus causing the clutch to drag and render gear changing difficult. Lubricant which is of too low a viscosity or is present in too small a quantity is apt to result in grabbing or cutting of the plates.

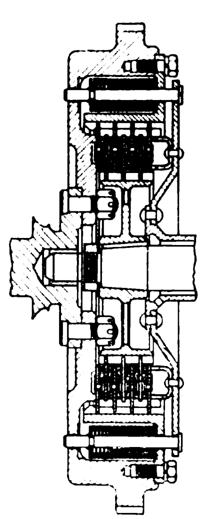

Fig. 21—The clutch used on the Packard single-six car

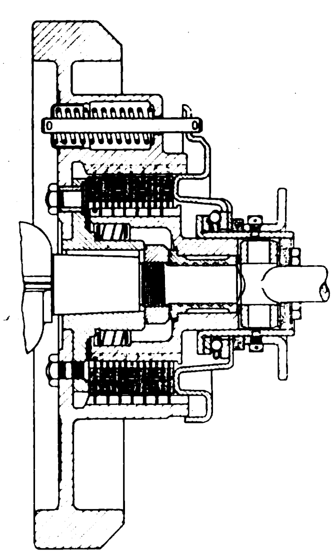

Fig. 22—The clutch which is used on the Reo passenger car

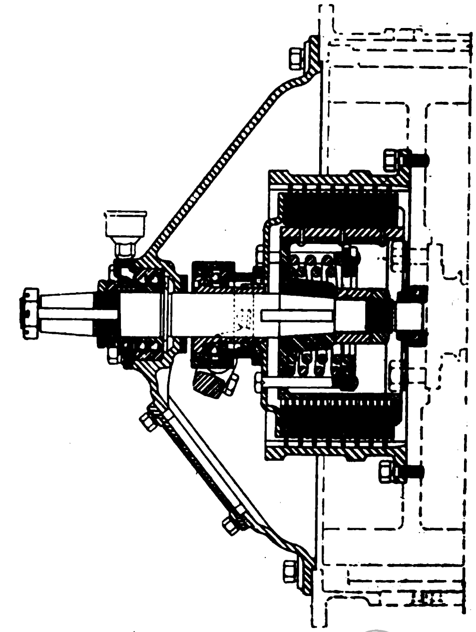

Fig. 23—The G. M. C. truck clutch

When oil is used the coefficient of friction is, of course, very much reduced, and in consequence many more plates are necessary for a given pressure and diameter to carry a given torque than when dry disks are employed. In consequence, the clutch which runs in oil is, for the same capacity, usually more expensive and heavier than the dry multiple disk type. For these reasons a great majority of the multiple disk clutches used to-day have disks of steel, with alternate disks faced with asbestos composition; these disks run dry, and are frequently not enclosed. Clutches of this type prove highly satisfactory in service when well constructed and properly proportioned. They are smooth in engagement, require practically no attention throughout the life of the facings, which last, as a rule, from 20,000 to 50,000 or more miles of car operation, and then are replaced easily. This type of clutch is compact and, since the driven members are light and of small diameter, gear changing is facilitated. While the number of parts used is greater than in other types, most of these are duplicate stampings, easily and cheaply made; hence, the cost of production need not be high and the clutch is readily made in a self contained easily removable unit. The large friction surface obtainable in multiple disk construction makes for long life, and the large number of surfaces permits the use of relatively light spring pressures and consequent easy action. In some cases fairly heavy springs and a small number of disks are employed without apparent advantage, except perhaps in the matter of cast.

Two distinct classes of multiple disk clutch are recognized in the American trade; the pin type, in which the drive or torque is taken through pins attached to the driving and driven members, and the gear tooth or key type, in which gear teeth, keys or their equivalent take the drive. The Hupmobile clutch shown in Fig. 19 and the Detlaff clutch illustrated in Fig. 20 are examples of the pin type. The Detlaff company makes also a gear type that is not shown here. It will be noted that the driving disks engage with driving pins, usually three in number, attached to the flywheel, while the driven disks engage with similar pins carried on the rear driven member which is, in turn, keyed or splined to the driven shaft connected to the transmission. In the Detlaff clutch the driven pins also carry the engaging springs, but in the Hupmobile design the springs are on separate pins, making a more compact layout, but adding extra parts. The friction facings in one case are riveted to the driving plates; in the

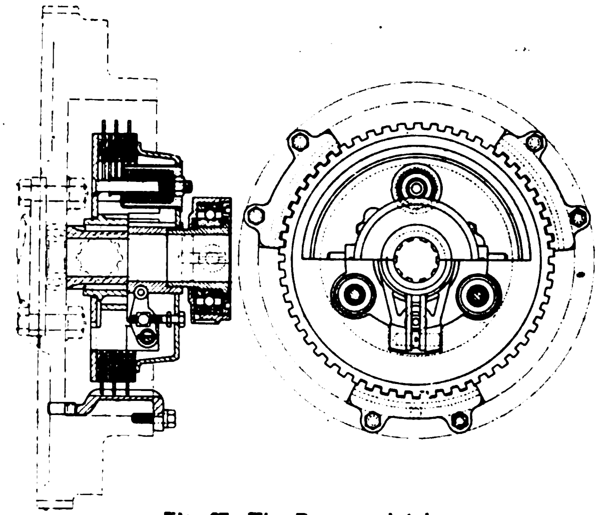

Fig. 27—The Browne clutch

other they are riveted to the driven plates, adding, it would seem, unnecessary weight to the driven unit. In most if not all cases the pin type of construction is less expensive and probably somewhat lighter than the gear or disk type, but it has one rather serious disadvantage as ordinarily constructed; it is apt to become noisy when wear takes place, because the holes in the disks through which the driving and driven pins pass cannot be made to fit the pins tightly, owing to the fact that the disks must be free to slide upon the pins and that the disks must be free to expand under heat, and consequently must have sufficient clearance to allow this expansion. Since the hole is either somewhat elongated or of larger diameter than the pin, only line contact between the two is possible without deformation or wear. Since the disks are relatively thin and the pressure due to torque is considerable, wear does take place and chattering frequently results when the clutch is disengaged.

Efforts to minimize wear are frequently made by providing larger bearing surface. This is done in the Detlaff design by punching the holes with a lip turned outward. In the Hupmobile clutch bushings are attached to the disks at the driving pin holes, but none are provided at the driven pin holes where, of course, the torque and pressure are greater. However, so long as round pins are employed, only line contact is theoretically possible. In some cases more than three pins are used, increasing the number

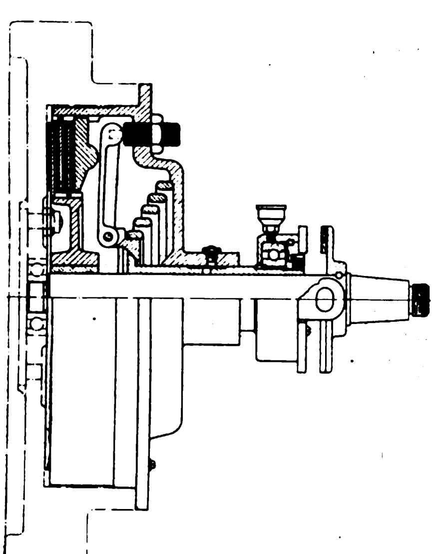

Fig. 24—The Hilliard clutch

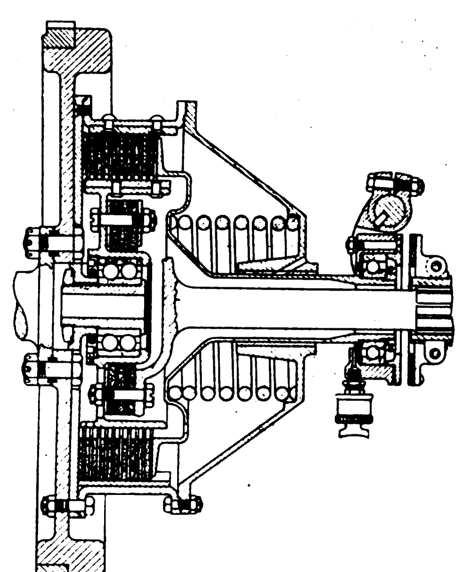

Fig. 25—The Locomobile clutch

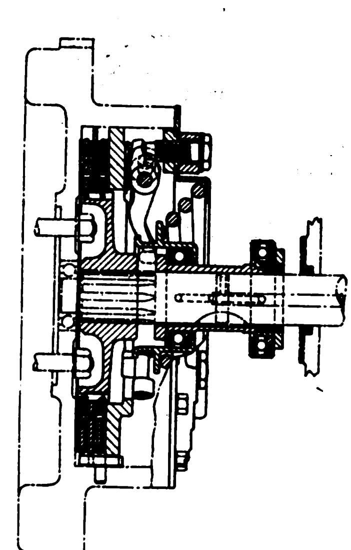

Fig. 26—The Merchant & Evans clutch

and total area of contact surfaces between pins and disks.

The gear or key type clutch goes another step further in this direction by increasing the number and area of the contact surfaces still more. Examples of the gear type of construction are the Packard, shown in Fig. 21; the Reo, in Fig. 22; G.M.C., in Fig. 23; and the Hilliard, in Fig. 24. The Locomobile clutch shown in Fig. 25 is an example of the key type, while the Merchant & Evans clutch in Fig. 26 is a combination of gear and key construction. The Browne clutch shown in Fig. 27 uses a straight side tooth on the driving disk, while the driven disks bear on substantial cast lugs. In clutches of these types an external driving ring, which can be an integral part of the flywheel, and an internal driven drum generally are employed. As a rule, the ring has either internal teeth cut therein or keys usually secured to its internal surface by rivets. The driving plates are formed to mesh with the ring teeth or keys, with sufficient clearance to slide freely in an axial direction. The drum has teeth or keys cut in or attached to its external surface, and these teeth, meshing with corresponding teeth or recesses in the driven plates, transmit the torque to the driven shaft to which the drum is splined or keyed.

The disks will bear equally on each tooth when well cut gear teeth are employed, thus reducing the unit pressure and wear as compared with the pin type. In the key type each key will bear equally over the full area of the notched surface of the disk, when properly made. Since the number of bearing surfaces can be made large, the aggregate surface is considerable and the unit pressure is much decreased relatively. In the Browne clutch shown in Fig. 27 the key type construction is carried a step further without using keys. The driving plates have straight side teeth which mesh with similar teeth broached in three separate gear segments attached to a standard S. A. E. flywheel rim, while driven plates have a large bearing surface on flat faced lugs cast integrally with the driven spider. The segments are stampings easily and cheaply produced in quantity; their use makes it unnecessary to use an expensive ring gear with internally cut teeth. Both the gear and the key types are apt to be less noisy than the pin type, but in general they are more expensive and are therefore used, as a rule, only on the more expensive and higher powered cars and trucks. They are better suited than the pin type to carrying a large number of plates and usually are able to transmit a higher torque. It will be noted that practice varies considerably in respect to the number of disks employed, the method of applying spring pressure and the location of the springs.

Since the torque capacity of any plate or disk clutch is directly proportional to the product of the number of surfaces between driving and driven members, the total pressure on the surfaces and the mean radius of the surfaces, it is evident that, for a given torque and mean diameter of clutch, the greater the number of disks is, the less is the pressure required and the less wear there is on the facings; the reverse also is true. The Merchant & Evans Co., which makes the clutch shown in Fig. 26, advocates the use of a small number of disks and therefore employs relatively heavy pressure. To get this without excessive pedal pressure, resort is had to levers that multiply the spring pressure. In so doing, a construction is employed similar to that used in the Borg & Beck and in the Hoosier plate designs shown in Figs. 14 and 15. In fact, the clutch shown in Fig. 26 might be termed a two plate type and is subject to the same disadvantages cited in connection with Figs. 15 and 16, since it requires an extra bearing and relative frequency of adjustment, but for the same diameter it has a larger wearing surface than the two types with which it is compared.

The other multiple disk clutches shown employ a large number of disks and, with the exception of the Hilliard clutch, which in some cases runs in oil and uses multiplied spring pressures, have direct acting springs giving lower total pressures on the friction surface than other types. In the G. M. C. truck clutch shown in Fig. 23, two centrally located springs are employed. In this case the outer end of the clutch shaft is carried in a ball bearing supported by a bell housing attached to the crankcase. This latter is conventional American practice where a separately mounted amidship transmission is used.

The Locomobile clutch shown in Fig. 25 is unconventional in that the double row ball pilot bearing is carried on a spigot extending from the flywheel, whereas this bearing is usually recessed within the flywheel, and in that it incorporates within the clutch a fabric universal joint. From this joint the driven shaft extends through a tubular extension of the pressure plate, but does not touch the latter. No bell housing is necessary in this case, although a separate amidship transmission is used. A single central spring is employed. Another rather unconventional construction which incorporates a universal joint as a part of the clutch unit is that of the Reo clutch shown in Fig. 22, in which the crankshaft is extended well beyond the clutch where a plain pilot bearing supports a block type universal at the end of the shaft connecting clutch and transmission. The ball thrust throw-out bearing is placed between the driving pressure plate and the driven throw-out collar, no other bearing being required between the two. Pressure is applied by three springs carried within the flywheel and equally spaced around the circumference of the pressure plate. There are six driven plates and only a relatively light spring pressure should be required.

The clutch used in the latest model of Packard passenger car is shown in Fig. 21. This is of the more or less conventional design used in connection with unit power plants. There are but three driven plates; hence, heavier spring pressure is required than would be necessary with more plates and the same torque. This pressure is supplied by four springs carried between the driven drum and the flywheel. An external multiplying linkage is employed between the clutch and the pedal to decrease the pedal pressure required to disengage the clutch. A plain pilot bushing is used within the crankshaft flange. The Browne clutch shown in Fig. 27 is one of the most recent designs of multiple disk clutch. While it deviates but little from conventional practice it incorporates several refinements in detail which indicate thorough appreciation of the problems involved both in use and in manufacture. For example, multiplying levers are used to decrease the throw-out pressure, which makes for light pedal pressures without external multiplying linkage, but the springs are direct acting and proportioned so as to require no adjustment during the life of the facings. The springs are contained within a pressed metal cup and carried on a thin metal tube which is turned over at its ends to prevent the spring from attaining its free length when the spring bolt nut is removed. The length of the tube is such as to enable the nut to catch a few threads on the bolt before seating on the spring. This greatly facilitates assembling, especially when the clutch is dismantled in a repair shop for the renewal of facings.

Adjustment is seldom required in the multiple disk type of clutch with direct acting springs, and then is made usually by turning up the nuts on the spring bolts. In the Browne clutch another and very convenient adjustment is provided. The multiplying throw-out levers each carry a threaded bolt with two heads. The outer head projects through a slot in the cover plate, and is adjusted to bear on the plate. The inner head bears on the inner surface of the cover plate when the clutch is disengaged.

As wear takes place in the friction disks the plate moves inward, leaving the bolt heads projecting above the surface. When they are seen to project about 3/16 in., they are simply screwed in until they again bear on the plate and the clutch is then again in adjustment. Such adjustment is required only once or twice during the life of the facings. Allowing all the bolt heads to bear on the plate assures uniform adjustment of the levers.

The Band-and-Shoe Types

Since band-and-shoe types of clutch are little used in automobile and truck applications, no special effort has been made to collect designs of this character, but one of the shoe type known as the Pfeiffer clutch is shown in Fig. 28. This consists of two semicircular shoes covered with asbestos fabric and arranged to engage the inner surface of the flywheel rim under influence of the spring and toggle mechanism shown. The action is somewhat similar to that of an internal expanding brake. The friction surface is fairly large and, since it is disposed at a rather large radius, the clutch should have high torque capacity with the multiplying linkage shown, even though the spring used be light. The weight and inertia of the driven member are considerable, however, and therefore gear changing will not be facilitated, while somewhat frequent adjustment of the toggles would doubtless be necessary on account of the large multiplication of pressure employed. Clutches somewhat similar to external band brakes have also been used in automotive vehicles, but these are seldom seen to-day and are therefore not described.

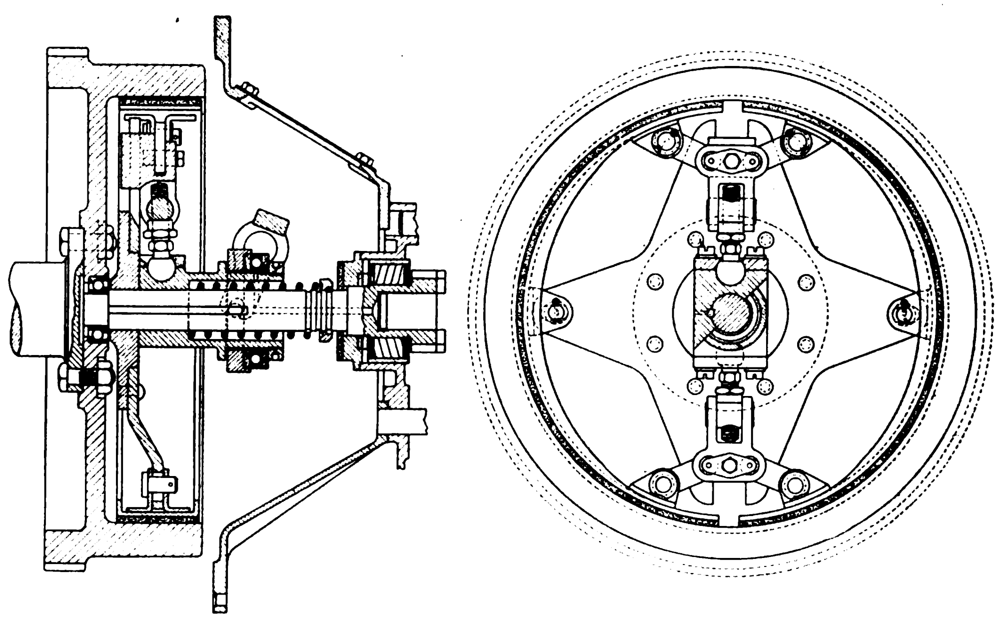

Fig. 28—The Pfeiffer shoe type clutch

Details of Design

All clutches require some type of bearing which will take the thrust imposed by the throw-out mechanism in disengaging. Ball thrust bearings are frequently employed. These are relatively cheap and give satisfaction when not required to carry radial as well as thrust loads, especially if the construction is such that they run only when the clutch is disengaged. When radial loads are imposed, either radial or angular contact ball bearings are usually employed. These types are somewhat more expensive than the straight thrust type, but are much better suited to carry radial loads; in fact, the straight thrust type is seldom recommended, although it is sometimes used when the radial load is light. It is then apt to become noisy and wear eccentric grooves.

When the thrust bearing is enclosed by a casing which is held against rotation by trunnion pins bearing upon the throw-out lever, which is a construction that is employed frequently, the bearing runs continually when the clutch is engaged and the engine is turning over. Although the load under these conditions is light, the continual running, frequently at high speed, inevitably causes wear, even though lubrication is facilitated with this construction. A design preferred by many engineers is that in which the bearing does not run continuously. The throw-out levers or ring are arranged to clear the thrust bearing except during the periods of disengagement, which are relatively very short as compared to the periods of engagement. When so arranged the bearing wears longer if properly lubricated, and even then requires but little lubricant. In fact, it is generally enclosed and packed with light grease which lasts in numerous cases for many months or even years of operation. In unit powerplants whose service is heavy and continuous, provision is sometimes made for lubrication by oil from the transmission by using a hollow clutch shaft drilled at a point near the bearing. If desired, the pilot bearing can be lubricated in similar fashion, but means to prevent excess oil from reaching the clutch facings are necessary; otherwise, in the dry type of clutch, slipping will occur. The pilot bearing, usually carried in a recess in the flywheel or crankshaft flange, is frequently of the radial ball type, but plain or oilless bushings are often used. The pilot bearing requires little lubrication, but is sometimes lubricated by oil seepage from a porous wicking plug, one end of which is supplied with oil under pressure in the hollow crankshaft of the engine. The driven members of some clutches, especially those of the cone type, are carried on spigots or extensions of the crankshaft. Usually, they have plain bushes, but ball bearings are used in some cases.

It is customary to provide a clutch brake to reduce the speed of rotation of the driven clutch members on disengagement and facilitate gear changing. This is usually in the form of a disk of small diameter arranged to bear on a flange or collar attached to the throw-out sleeve, and in general is made of fiber or asbestos composition. The brake disk is fastened to the gearbox as a rule, in the case of unit powerplants, or to the bell housing when a separate gearset is employed, but it is sometimes allowed to float on the clutch shaft between the thrust bearing and some flatfaced stationary member. The clutch brake is of course more important with clutches having heavy driven members with considerable inertia than with lighter driven members, and is not essential in some types, especially the multiple disk type in which the floating driven members are light and of small diameter and decelerate rapidly, due perhaps to a degree of dragging which is not, however, sufficient to cause the difficulties which a more positive dragging incurs. In plate and disk clutches it is necessary to provide means whereby the driven members shall be free to float in an axial direction on disengagement, even after some wear takes place. In some designs small relief springs are arranged to give more positive disengagement, but these are not essential except perhaps in some designs in which plate or disk runs in oil, which may cause adhesion under certain conditions.

[4] (*A*)—American, (*C*) Clutch, (*E*)—English, (*P*)—Passenger Car and (*T*)—Truck.
[5] Figures are for 3-ton truck.
[6] Figures are for 5-ton truck.
[7] Bronze indicates bronze plate without facing material. *M*—Molded asbestos composition and *F*—Woven asbestos fabric.
[8] Areas given are computed from the diameter and width without any allowance for rivet holes or depressions for other holding devices.
[9] Figures given are the arithmetical mean radii.
[10] Figures given include the flywheel or members attached rigidly thereto, taken as one member when the friction face bears upon the flywheel or the rigidly connected member.
[11] Figures include only members which transmit torque directly from driving members; a driven member made up of two or more pieces is considered as one member, and driven members such as levers and throw-out sleeves which do not transmit torque *directly* from driving members are not included.
[12] Figures in parentheses are uncertain.
[13] When two figures are given, the clutch maker furnishes springs giving either pressure, or some intermediate pressure.
[14] Figures are presumed to be the maximum pressures when the clutch is new and properly adjusted. When toggles are used to multiply the spring pressure, any slight alteration in the position of the toggles, due to wear or lack of adjustment, can make marked variation in total or unit pressure.
[15] In some cases these figures indicate the actual or computed maximum torque capacity, and in others "safe" or "recommended" capacity. In some cases the manufacturer makes clutches of different capacity than the model listed, or will vary the capacity to suit conditions by a variation in the number of discs, friction material or spring pressure.
[16] The first figures are the capacity when arranged to run in oil and the others are the capacity when used dry.
[17] This figure corresponds to the manufacturer's recommendation. Other figures in this column are actual ratios employed presumably with the clutch new or in perfect adjustment.
[18] Figures in this column are the actual pressures used or reported used by the respective manufacturers.
[19] Univ.—Universal joint. In nearly all clutches the driven members, and in some types the driving members also, must be allowed a certain free axial motion upon release, and some member such as keys, splines, gear teeth or pins which transmit torque and at the same time allow axial motion are therefore provided and these members are listed in this column. The pin or block of the universal joint frequently performs this function, especially in the case of cone clutches.
[20] Data in this column refer to levers which rotate with and form a part of the clutch, and not to non-rotating throw-out levers external to the clutch.
[21] Data in this column refer to adjusting means within the clutch. External adjusting means are often provided but not referred to here.

Some details of spring construction have already been discussed, but a few items in this connection remain to be considered. The space allowed for springs and the desirability of compactness in design make it necessary in most cases to use rather short springs. These are often too stiff; that is, for a small change in length, the pressure change is considerable. The result is that wear on the friction surface decreases the pressure enough to cause slippage. This condition can often be bettered by a change of spring section and material without variation in overall dimensions or, in other words, by an intelligent design of the spring. In many cases the springs are mounted so that the decreased pressure occasioned by wear can be compensated by a simple adjustment but, with the direct acting spring, this adjustment is not necessary if the springs are designed properly and if the capacity of the clutch is correct in relation to maximum engine torque. When several springs are used it is desirable to have them of uniform strength and flexibility, adjusted to give equal pressure to prevent unequal wear and cocking or binding upon release, and with smooth action engagement, but reasonably satisfactory operation is sometimes obtained in spite of failure to comply closely with these general rules. Some clutch makers prefer a single centrally placed spring, claiming that it gives a more uniform pressure; but this is dependent upon other factors than the spring. This is indicated by the construction used in the Hilliard clutch shown in Fig. 24, wherein a spherical bearing-surface is provided between the pressure ring carrying the multiplying levers and the throw-out sleeve, with the intention of insuring equal pressure at each fulcrum point on the pressure plate. Multiple springs are often recessed within the flywheel or placed in pockets of pressed metal in the annular space between the disk facing and the hub. This gives a neat external appearance, reduces windage, facilitates enclosure and minimizes danger of injury when the clutch is turning.

It is not my intention to discuss the theory of clutch

design at length, but rather to comment briefly on certain simple basic factors which must be well understood before an intelligent design can be laid down. The maximum torque capacity of any clutch is given by the equation

$$T = PNrf$$

where

T = the maximum torque capacity in pound-feet
P = the total pressure on the friction surface in pounds
N = the number of engaging surfaces
r = the mean radius of the friction surface in feet
f = the coefficient of friction

Concerning the pressure factor, it is possible theoretically to build a clutch of any desired capacity by simply increasing the pressure on the friction surface, but there are practical limits beyond which it is impracticable to go. A 60-lb. pedal or throw-out pressure is about the maximum permissible, except perhaps in certain truck applications. For comfort in driving, 30 lb. is considered the permissible maximum pressure by some designers, while lighter pressures are desirable in cars intended for ladies' use. It is general practice among American car and transmission manufacturers to use a pedal measuring about 11 in. on the long arm and from 1½ to 2½ in. on the short arm which actuates the clutch. This gives an average leverage of 5.5 to 1. With this ratio and a maximum pedal pressure of 60 lb., the pressure on the short end would be 330 lb., but this pressure should preferably not exceed 165 lb. A compound reduction by links and levers or cams external to the clutch can be employed, but this involves extra parts which are not required otherwise. If direct acting clutch springs are to be employed, a pressure of 165 lb. is not sufficient to prevent slippage with the average engine unless the number of friction surfaces or the mean radius of the surface is increased unduly. Two alternatives are employed, so far as the clutch proper is concerned, (*a*) the use of levers to increase the pressure on the friction surface and (*b*) the use of wedging action to increase the pressure on the friction surface. The advantage and disadvantage of each method has been pointed out in the discussion of the various types of construction.

By reference to the illustrations and to Table 1 it will be seen that many clutch designs in which direct acting springs are employed involve the use of much greater total pressures than 165 or even 330 lb. To decrease the pressure required for disengagement, levers of various forms are incorporated within the clutch. This makes possible the use of a single plate or of fewer disks without involving the chief disadvantage of levers which multiply spring pressure. From the foregoing it will be seen that there are several methods of varying the factor P in the capacity formula and thus varying directly the clutch capacity, but it should be borne in mind however that, other things being equal, the wear on the friction face is proportional to the unit pressure on the surface; hence it is an advantage to keep the unit pressure low.

An inspection of the capacity formula shows immediately that the capacity of a clutch is directly proportional to the number of friction surfaces engaging. When floating disks are employed between driving and driven members, slip is divided between the two faces; hence, but one face is considered in determining the factor N in the formula of capacity. It is possible to double the capacity of a single plate clutch by simply adding a second plate and a friction ring. The advantage of the multiple disk type in this respect is obvious. In this type it is possible to adapt the same clutch to engines of different capacity readily by merely changing the number of plates. The number of plates used will determine, at least to some extent, the ease of engagement or how gradually the full load is picked up upon engagement of the clutch. Increasing the number of plates and decreasing the spring pressure increases the "softness" of engagement and facilitates starting without sudden shock or undue strain on the mechanism.

For practical purposes the mean radius of the friction surface can be taken as equal to one-half the sum of the maximum and minimum radii. The torque transmitted obviously increases as the distance from the center to the point of application of pressure increases, and in direct proportion to this distance; hence, a large clutch diameter is desirable so long as the inertia of the driven member is not too great. The maximum diameter is controlled, however, largely by the size of the flywheel and by the cost of construction, which increases considerably with size. For a given outside diameter of friction surface, the mean radius can be increased by using a narrow facing, especially on plate and disk clutches. Although this decreases the area of surface, practical experience has shown that, within certain limits, a narrower facing wears longer than a wide facing. This apparently is because of the greater uniformity of wear over the entire surface, due no doubt to the fact that the rubbing speed at the outer diameter of a wide annular surface is much greater than at the inner diameter.

Coefficient of Friction

Since by definition the coefficient of friction between two surfaces is the ratio obtained by dividing the force required to slide one surface over the other by the pressure on the surface, it is evident that, as applied to clutches, the coefficient is the ratio of the maximum torque each surface can carry to the total pressure on that surface. The coefficient varies greatly with the nature of the surface and its condition, especially with respect to lubrication. Between smooth metal surfaces wetted with oil, it is about 0.07. Woven asbestos fabric on smooth steel gives an average coefficient of about 0.3, but this varies considerably with wear, the temperature and the nature of the impregnating material used in the manufacture of the fabric. If the impregnating material contains paraffin or other substances which, under the influence of heat, act to some extent as lubricants, the coefficient will decrease as the temperature rises, so that a clutch which performs well when cool sometimes starts suddenly to slip when it has become heated by the slipping that always occurs on engagement. Frequently, repeated engagements such as occur when driving in traffic or careless handling during periods when the clutch is intentionally allowed to slip, sometimes raise the temperature to 500 deg. fahr. or higher; hence, the facing material must be capable of withstanding this temperature and the factor of safety as regards capacity should be sufficient to permit operation even with the reduced coefficient at high temperature. The friction coefficient of woven linings is known to vary through a wide range. One engineer who has made tests with woven facings reports coefficients varying from 0.27 to 0.38. It is considered good practice to use a clutch that has a normal torque capacity when new of 1.6 to 2 times the maximum torque of the engine, although some engineers state that smoother action results when the torque capacity of the clutch is only slightly in excess of that of the engine.

A clutch that will carry a given maximum torque indefinitely when once fully engaged will not always pick up this load without slipping for a relatively long period during which excessive heat is generated. One investigator states that experiment has shown, in the case of multiple-disk clutches at least, that a desirable softness of engagement is secured without undue heating by a clutch that will slip from 50 to 60 revolutions when suddenly assuming full load, and that this slip is obtained

when the maximum load carried averages 70 per cent of the total load that the clutch will carry without slip when fully engaged. Within the last two or three years, facings of molded asbestos composition have come to be used widely. They are said to have a friction coefficient of 0.5 and to be more durable than other facing materials. They are of uniform texture, can be made in quantity to close tolerances and do not require a joint secured with wire staples such as is generally employed with the woven fabric. It should be noted that the coefficient of friction is independent of the area of contact surface. For this reason a narrow facing under a given pressure will carry the same torque as a wide facing having the same mean radius, but the unit pressure will of course be greater on the narrower facing. This will tend to cause greater wear, but the wider surface, as pointed out, does not always wear longer because of the greater difference in speed at inner and outer diameters. The ideal condition in this respect is approached most closely by the use of a number of relatively narrow surfaces, thus giving a large total area, a consequent long life and a more gradual picking up of the load, without causing wide differences in speed between the various parts of the contact surface.

In Conclusion

From the foregoing analysis of factors entering into the capacity formula, it will be seen that torque capacity can be made to vary by changes in each of the four factors involved. In other words, the same torque can be obtained by a great number of combinations. The best combination is that which gives the longest life, requires the least attention, is the smoothest in engagement, has the lowest inertia and is the least expensive to manufacture. For passenger car use at least, the multiple disk type seems to fill best the greatest number of these conditions, but it is evident from the number of other types used that engineers are far from being agreed on this point. In this connection it is worthy of note that there is wide variation in multiple disk clutch design. When the price must be kept as low as possible, the number of plates is usually reduced to the minimum and the pressure on the discs is increased; but when the cost is secondary to the smoothest action on engagement, the number of plates is increased and the pressure reduced, at the same time prolonging the life of the facings by adding to the total wearing surface.

The data given in the table have been gathered from a variety of sources and no claim is made for their absolute accuracy. Many of the dimension figures were obtained by scaling blueprints and, consequently, they may vary slightly from the actual dimensions used. It will be seen, however, that practice varies so widely in many particulars that the comparisons afforded by the figures given are close enough for practical purposes. It is the hope and belief of the author that the data and drawings collected here will prove useful to engineers who are called upon to design clutches or to make a selection for a given purpose from among the various types of clutch available.

Some Production Problems Which Influence Design

(*Continued from page* 1260)

3. When pieces are to be chucked for turning, boring or threading operations it is an advantage to do as many operations as the machine will admit of doing without rechucking.

4. Close tolerances tend to increase production difficulties and slow down production.

5. Stampings and screw machine parts are in general the least expensive parts to make, providing the quantity is large enough to offset the cost of dies and machine set-up.

6. Die castings are in general cheaper than sand castings when the quantity is large enough to cover cost of dies and machine work is to be minimized.

7. In some instances it is cheaper to use, at a higher price per pound, a soft or more easily machined metal in place of a harder and slower machining metal—for example, aluminum in place of cast iron—for certain applications, because of greater ease and speed in machining.

8. Other things being equal, it is desirable to design a piece in such a way that the machine work can be completed with one setting in one machine.

9. It is sometimes cheaper in quantity production to purchase or build a special machine tool to do a given job than to attempt to adapt the design to existing tool equipment.

10. It is in general desirable to consider in design the adaptability of the piece to good and economical types of jigs and fixtures. Much expense can often be saved by providing suitable bosses or other locating points, or by changes in form which facilitate clamping in jigs, centering in chucks, etc.

11. Similar parts used for similar purposes can often be made identical by the exercise of reasonable ingenuity, with consequent saving in tool equipment, parts stock, material supplies, etc. Spring brackets used on the right and left side of the car, or for front and rear springs can often be made interchangeable instead of right and left.

12. Use of standard forms of fittings, such as clevices, bolts, etc., is nearly always economical, not only in first cost, but in securing ready interchangeability, use of standard tools, decrease in stock parts, etc.

13. In design the stresses imposed during manufacture of the piece must be considered, since distortion during machining or heat treatment may cause poor fit or rejection in assembly.

can be prevented by clamping or application of pressure during quenching or cooling operations.

When a new company is starting on the design of a car to be produced in quantity or is organizing for production in a large way of some important unit, the design may well be quite different from that which would be laid down for a company already in business with equipment that must be utilized for the purpose. In the former case equipment especially adapted for the most modern and rapid production methods can be purchased from stock makes or specially designed and built for the purpose, while in the latter case certain limitations are inevitable which may or may not prove a real handicap. The intensive and rapid development of machine tools in the past few years has, however, worked a revolution in production methods, so that the manufacturer whose equipment has not been kept up to date may well consider the relative advantage of continuing production with old equipment and retooling to enable him to realize the advantages of the most modern equipment. When the quantity warrants, even well-equipped manufacturers are in many cases designing and building or having built for them tools devised especially for rapid and accurate production of given parts. Such tools minimize labor and handling costs and insure more accurate work than might otherwise be secured only by more elaborate arrangements.

Fits, Tolerances and Heat Treatments Applied in Production

A valuable collection of data covering actual practice employed by many manufacturers in the production of all parts used in a heavy truck. The same fits, tolerances and heat treatments are applicable in the production of parts for passenger cars, light trucks and other automotive vehicles.

By C. T. Bates

THE data given in this article cover the practice employed in many plants in the production of parts for the Class B Military Truck developed for the United States Army by a committee of prominent American engineers. It will be recalled that the design incorporates many of the best points used in the design of American heavy duty trucks. **The data can, to a great extent, be applied to general automobile as well truck construction and should serve to give the industry practical information in relation to the various fits, clearances machining tolerances and heat treatments necessary to produce a machine thoroughly practical in every particular.**

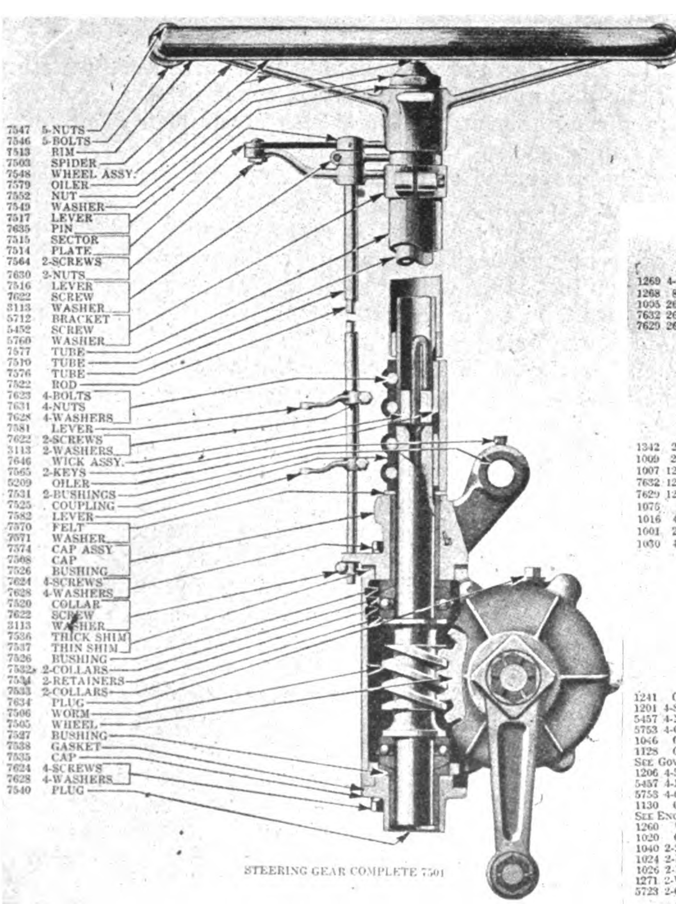
These data are the result of years of experience of many engineers and production men in this country and have been thoroughly proven by the production of thousands of trucks. They apply particularly to a truck of five tons capacity having a chassis weighing 8500 lb. and an engine developing 48 hp. at 1000 r.p.m.

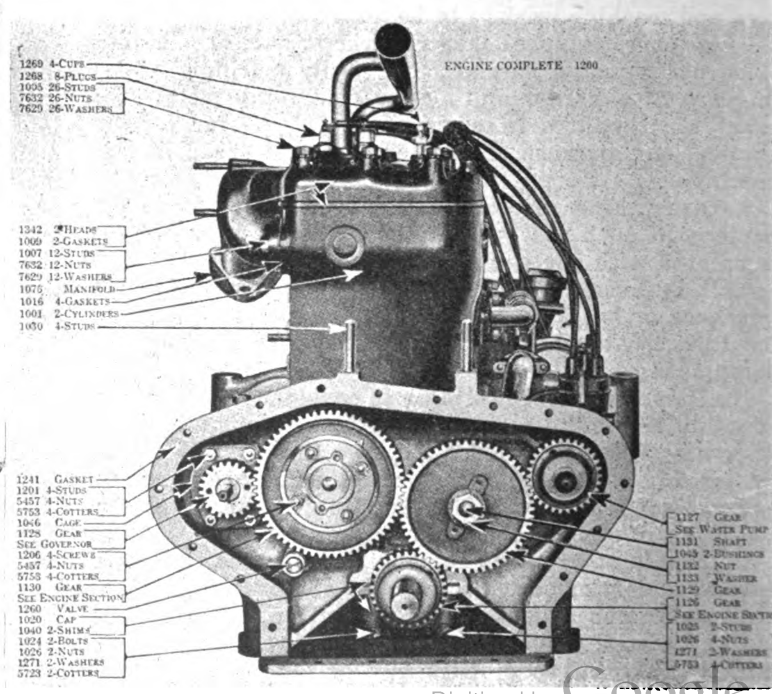
The machining limits in many cases are close, but it has been found in practice that the results obtained in the assembly and performance on the road more than make up for the slight extra cost involved in working to close limits. The material and heat treatments herein specified are such as to give the best results it has been found possible to obtain.

Engineers frequently desire to know what is practical in the way of material, heat treatment, machine limits and the various running or press fits for certain parts. Such information could heretofore often be obtained only by prolonged tests and experiments which frequently entailed serious delays and an expenditure of much money. The various books on the theory and design of automobiles, motor trucks and parts have given for the most part information of a general nature and have omitted much specific information which is essential to practical production in the shop. This article gives much data intended to fill this gap.

General Description of Truck Units

The following is a brief description of the various motor truck units to which these data relate.





STEERING GEAR DATA

7506—WORM

O. D., 2.515-2.510; P. D., 2.125
Left hand
Double thread, 29 deg.
Ratio 10½ to 1
Lead 1⅝
Angle 13 deg., 41 min. 35 sec. Pitch, .8125
Width of tool nose, 272
Root diameter, 1.651
Whole depth of tooth (4329 theoretical) (.429-.432 actual)
Addendum (.1961 theoretical) (.192-.195 actual)
Carbonize worm 1/32 of an inch deep to show 70-80 sclerescope, heat treat shank to show 30 minimum sclerescope sand blast after hardening.

7505—WORM WHEEL

Left hand
Ratio 10½ to 1
Number of teeth, 21
Throat diameter, actual, 5.808-5.798
Root diameter, 4.957
Curvature radius, .866
Face angle, 68 deg.
Circular pitch, .8125; pitch diameter, 5.431
Cutting angle, 13 deg. 41 min. 35 sec.
Whole depth of tooth, .433 theoretical; actual, .421-.426
Carbonize wheel 1/32 deep to show 75-90 sclerescope on top of teeth. Heat treat shank to show 30 minimum sclerescope, sand blast after hardening.
Sides of teeth to be file hard. Wormshaft taper end 1 inch taper per foot, Chamfered corners of same 1½ inch taper per foot.
Worm included angle 68 deg. (gear tooth)
Radius of tooth on P. D., 1.062; radius top of tooth, 1.023; radius centers, .177 apart. Center line of worm wheel to center-line of worm 3.778. (Gears). Center line of cases, 3.779-3.777

Valve Timing	Inlet	Exhaust
Open	Past top 15 deg.	Before bottom 45 deg.
Closes	Past bottom 35 deg.	Past top 5 deg.
Lift	11/32 in.	11/32 in.
Valve diameter O. D.	2⅜ in.	2⅜ in.
Seat angle	45 deg.	45 deg.
Exhaust or inlet throat diameter	2⅛ in.	2⅛ in.
Exhaust or inlet valve clear diameter	2⅛ in.	2⅛ in.
Base circle clearance	.005	.005
Tappet roller diameter	.9385-.9355	.9385-.9355

Hold "exhaust closes" and "inlet opens" to P. or M. ⅛ in. on flywheel.
Hold "exhaust opens" and "intake closes" to P. or M. ¾ in. on flywheel.
Scleroscope hardness, minimum minutes, 65-70 desired on cams. and bearings.
Material SAE 1020 carbon .15-25; manganese .040-.060; phosphorus .045; sulphur .05, case harden.

Cylinders parallel within .003.
Cylinders bore not over .001 excentric or .002 taper.
Cylinders hydrostatic test 60 lbs. cold finished with studs in place.
Cylinders wall thickness 3/16 in.
Cylinders water jacket 5/16 in.
Crankshaft and crank pin bearings tolerance for length between shoulders +.002 – .000 in.
Crank pin center to shoulder out of center ±.005 in.
Crankshaft allowance for grinding 1/32 in. on diameter.
Crankshaft forging allowance for finish ⅛ in. all around on finished surfaces.

Transmission gear shaft allowance for grinding, .020-.025 in.
Transmission gear forgings allowance for finish $\frac{1}{16}$ in. all around.

WORM GEAR DATA

REAR AXLE

6224—WORM SHAFT
Threads, 4 R. H.
Linear pitch, 1.1562
Pitch diameter, 3.265
Lead, 4.625
Lead angle, 24 deg. 20 min.
Full depth of thread, .723
Addendum, .3352
Dedendum, .3878
Normal pitch, 1.0535
Pressure angle 30 deg.
Normal pressure angle 27 deg. 44 min.
Outside diameter (grind) 3.936-3.934
Angle between teeth, 60 deg.
Thickness of tooth at pitch diameter line .5781
Root diameter, 2.4894

Material, 3120 SAE
Carbonize $\frac{1}{4}$ deep heat treat to 1550 and quench draw to 700 (whole shaft)
Treatment from rear end to forward bearing shoulder, submerge in lead at 1400 and quench, draw to 350 deg.
Sclerescope from rear end to forward bearing shoulder 70 to 85
Sclerescope from forward bearing shoulder to front end 40 to 50.

6222—WORM WHEEL
No. teeth, 38 right hand
Pitch, 1.1562
Pitch diameter, 13.985
Throat diameter, 14.625
Lead, 4.625
Lead angle, 24 deg. 20 min.
Addendum, .3352
Dedendum, .3878
Normal pitch, 1.0535
Pressure angle, 30 deg.
Normal pressure angle, 27 deg. 44 min.
Make normal tooth thickness at pitch line .5355 to allow for back-lash
Make radius on points of hob teeth .084 and at root of teeth .168

Material—make from best grade gear bronze. Tensile strength 35,000 to 40,000 at least. Copper 89; tin 11. Brinell 70 to 95. Chill castings.

6208—GEAR AND CASE CENTERS
Carrier centers 8.627-8.623
Worm and worm wheel centers, 8.625

Engine—The engine is of the four-cylinder heavy duty L-head type. The cylinders are cast in pairs and have removable heads. The crankshaft is of the conventional three bearing type with integral flange at the rear to which the flywheel is bolted. The camshaft has integral cams, runs in three bronze bearings and is driven by a train of helical gears in the front of the crankcase. The connecting rods are of the four-bolt type. The piston pin is held fast in the piston by a screw threaded into the piston pin boss and extending through the pin into the top side of the boss. The oiling system is of the full force feed type, the oil being circulated by a gear pump, located in the bottom of the crankcase, to the crankshaft bearings through tubes cast in the case. It is then forced through the crankshaft to the connecting rod bearings and thence through tubes attached to the connecting rods to the piston pins. The normal pressure at 1000 r.p.m. is 15 lb. per sq. in.

Gearset—The transmission is located amidship and is of four-speed selective construction driving direct on fourth speed. It is supported at three points with trunnion at the front end. Its construction is conventional throughout.

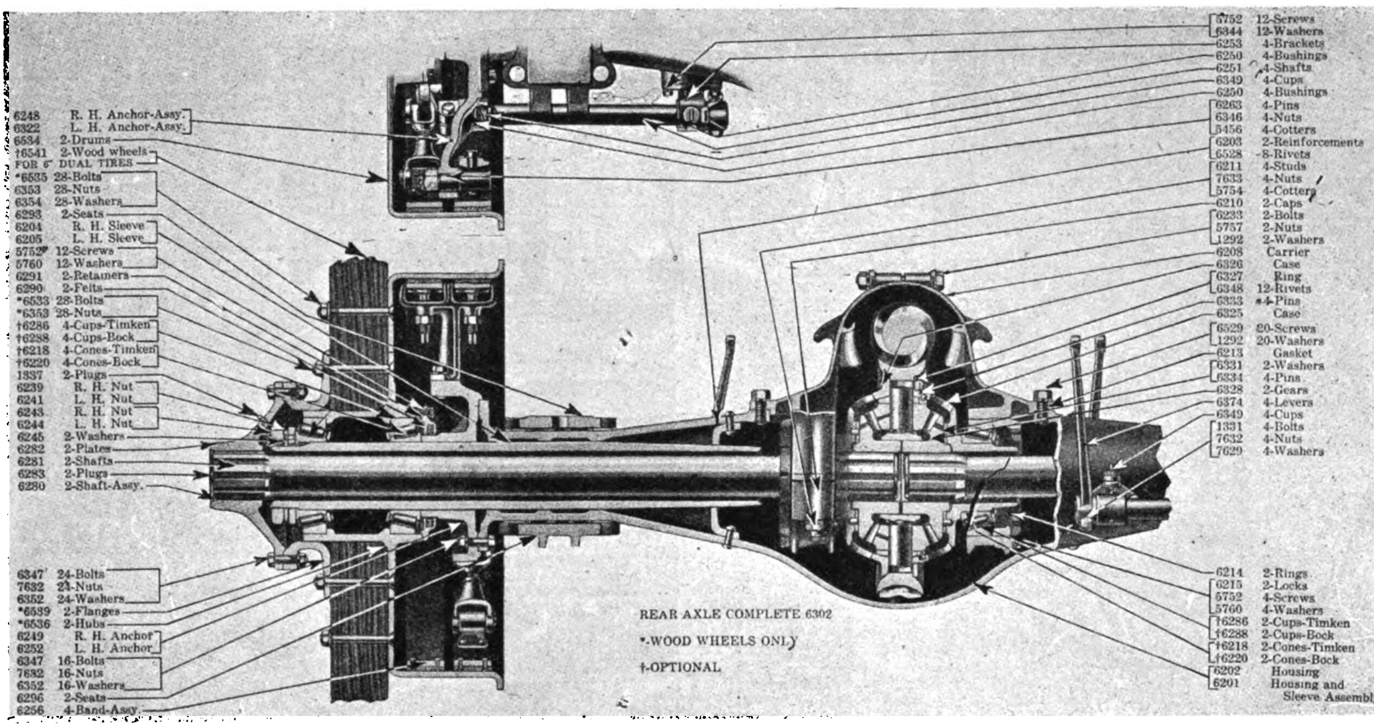
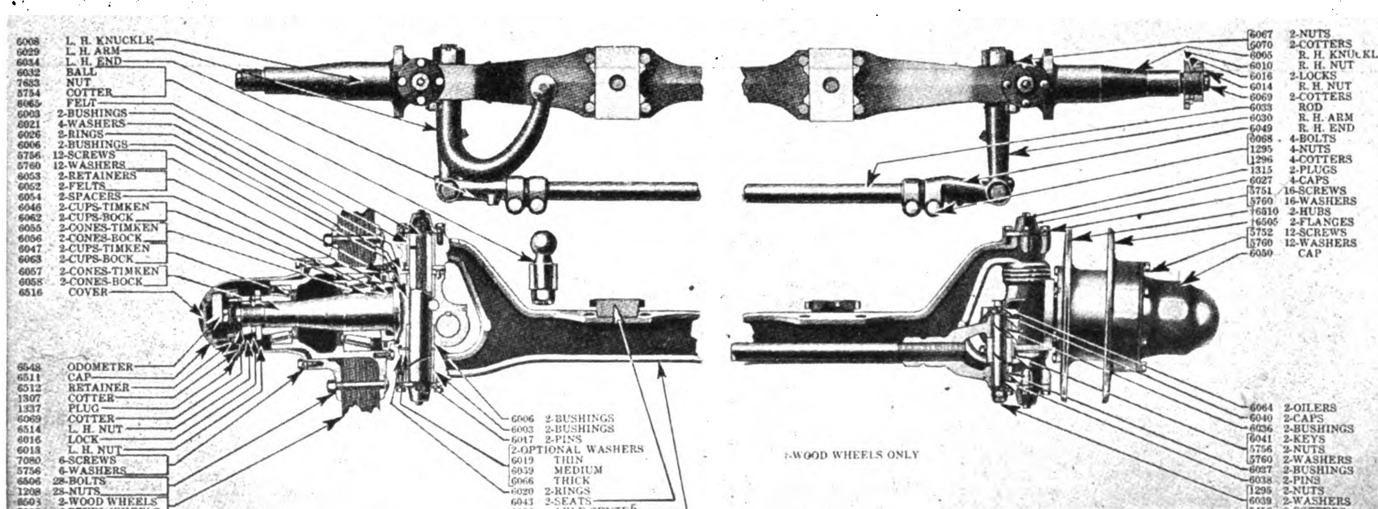
Transmission Complete—5501

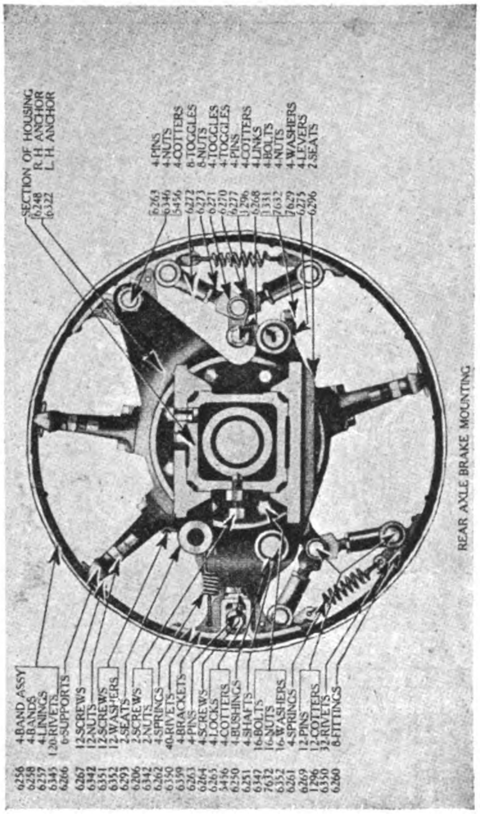


FRONT AXLE COMPLETE 6060

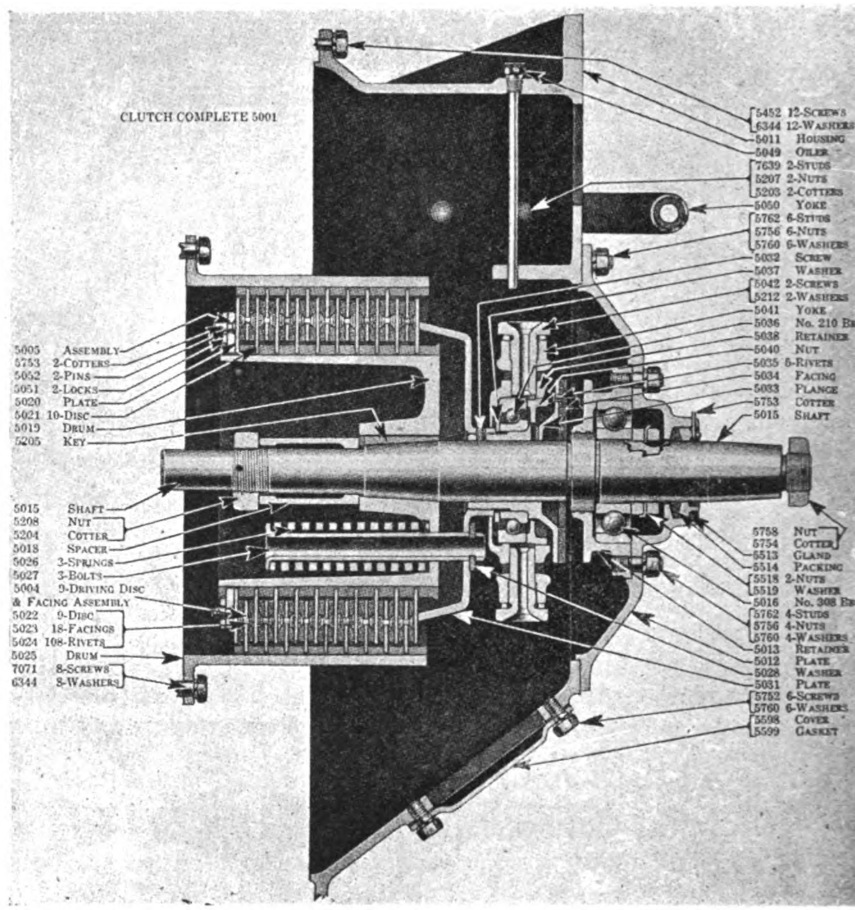


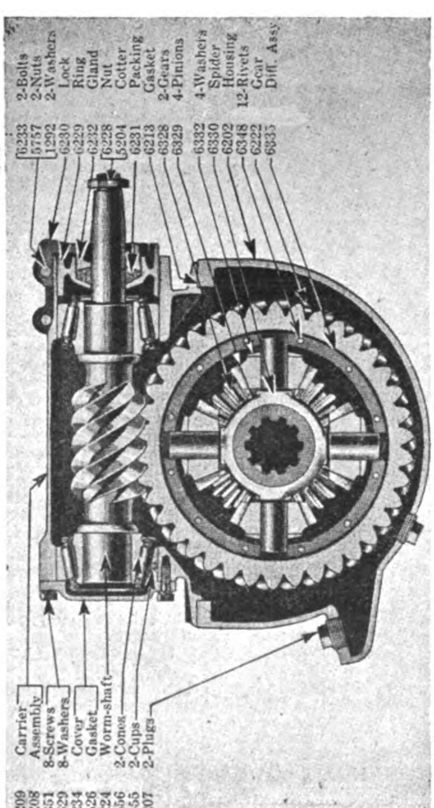
Sheet Steel Specifications

Use		Commercially Known	Requirements
Mud pans, muffler shells	Bessemer or open hearth black steel sheets	One pass cold rolled and box annealed	High finish or extra deep drawing properties not necessary. Should be free from detachable scale, cracks, rust, etc.
Motor hoods, mud guards	Open hearth steel sheets	Full pickled, full cold rolled and re-annealed	Smooth, dense and highly polished surface suitable for two coat dip enameling on one side, not dead soft but sufficiently so that 20 gauge or lighter will bend over itself without signs of fracture. Defects such as cracks, roll marks, waves, dents, buckles, pits, blisters, scratches, rust, etc., not permitted
Parts requiring deep drawing properties but not high finish	Open hearth steel sheets	Extra deep drawing hot rolled steel, pickled and oiled	Should be free from detachable scale, cracks, blisters, rust, etc.
Body panels (drawn)	Open hearth steel sheets	Deep drawing full pickled, full cold rolled and re-annealed	Should have a smooth surface absolutely free from any injurious imperfections, extremely high lustre not required. Drawing properties should be sufficient to meet the requirements as shown by the drawings. Defects such as cracks, waves, dents, buckles, pits, blisters, scratches, rust, etc., not permitted
Body panels (plain)	Open hearth steel sheets	Full pickled, full cold rolled and re-annealed	Extra drawing properties not required; should have smooth surface free from cracks, waves, dents, buckles, pits, blisters, scratches, rust, etc.
Gasoline tanks	Open hearth steel sheets	12 lb. long terne sheets	Sheets with moderate number of small blisters, pits or turned corners will be rated as seconds and should not exceed 25% of the number of prime sheets. Sheets should be uniformly coated with 75% lead and 25% tin. Analysis of coating on 20 sq. in. area should show not less than 0.35 oz. per sq. ft.
Small drawn and embossed stampings	Open hearth steel strips	Hot rolled strips, pickled and oiled	Strips should be free from detachable scale, cracks, blisters, rust, etc.
Small parts requiring deep drawing but not a high finish	Open hearth steel strips	Deep drawing hot rolled steel, pickled and oiled	Strips should be free from cracks, blisters, rust, etc.
Small ordinary drawn and embossed stampings requiring good finish	Open hearth steel strips	Cold rolled strip steel	Strips should have smooth surface free from cracks, blisters, rust, etc.
Brake bands, shims, etc.	Full cold rolled open hearth steel strips	Hard cold rolled strip steel	Strips should have clean, smooth surface free from scale, cracks, blisters, rust, etc.



REAR AXLE BRAKE MOUNTING





Fits Employed for Various Parts

Fit numbers at the left, such as 1, 2, 3, and 4, indicate the class of fit as follows: No. 1—Press fit; No. 2—Running fit; No. 3—Clearance fit; No. 4—Shrink fit.

7224	3	Front spring shackle bolt	.872 .871 (grind)	1020 SAE
7226		Front spring shackle bolt hole	.873 .872 (ream)	1025 SAE
7415	3	Rear spring front bracket pin	1.243 1.241 (grind)	1020 SAE
7035		Rear spring front bracket	1.247 1.246 (ream)	Steel casting
7409	1	Rear spring rear shackle bushing	2.004 2.002	26 SAE
7408		Rear spring shackle—rear	2.000 1.998 (ream)	Steel casting
7416	3	Rear spring rear shackle pin	1.243 1.241 (grind)	1020 SAE
7408		Rear spring shackle pin bore	1.247 1.246 (ream)	Steel casting
7224	2	Front spring shackle bolt	.872 .871 (grind)	1020 SAE
7207		Front spring eye bushing hole	.876 .872 (ream in place)	26 SAE
7416	2	Rear spring shackle pin	1.243 1.241 (grind)	1020 SAE
7298		Rear spring front eye bushing hole	1.252 1.247 (ream in place)	26 SAE
7403	2	Rear spring shackle bar	1.746 1.744 (grind)	1114 SAE
7409		Rear spring shackle bar bush. hole	1.7500 1.7485 (ream in place)	26 SAE

Fits Employed for Various Parts—*Continued*

Fit numbers at the left, such as 1, 2, 3 and 4, indicate the class of fit as follows: No. 1—Press fit; No. 2—Running fit; No. 3—Clearance fit; No. 4—Shrink fit

TRANSMISSION

Part No.	Fit No.	PART			MATERIAL
5534	1	Transmission countershaft	2.1315	2.1305 (grind)	3320 SAE
5531		Countershaft gears	2.130	2.129 (grind)	2320, 3320, 2345, 3350 SAE
5592	1	Idler gear bushing	1.628	1.627 (turn)	26 SAE
5591		Reverse idler gear	1.625	1.624 (grind)	2320, 3320, 2345, 3350 SAE
5593	3	Reverse idler gear shaft	1.249	1.248 (grind)	2320 SAE
5511		Reverse idler gear shaft bore in case	1.250	1.249 (ream)	Aluminum SAE-31
5551	3	Trans. main shaft—top of keys	2.245	2.240 (grind)	2320, 3320, 2345, 3350 SAE
5562		Trans. sliding gears—key bottoms	2.290	2.310 (broach)	2320, 3320, 2345, 3350 SAE
5551	3	Trans. main shaft—bottom of keys	1.9105	1.9085 (grind)	2320, 3320, 2345, 3350 SAE
5562		Trans. sliding gears—key tops	1.913	1.912 (grind)	2320, 3320, 2345, 3350 SAE
5551	2	Trans. main shaft—key width	.556	.553 (grind)	2320, 3320, 2345, 3350 SAE
5562		Trans. sliding gears—keyway	.564	.560 (broach)	2320, 3320, 2345, 3350 SAE
5571	2	Trans. shift forks—bottom jaws	2.770	2.760	1025, 1035 SAE
5562		Shift fork groove diameter	2.750	2.745	2320, 3320, 2345, 3350 SAE
5571	2	Trans. shift fork—thickness	.433	.429	1025, 1035 SAE
5562		Trans. shift fork groove—width	.438	.436 (grind or polish)	
5563	3	Sliding gear hubs	3.875	3.8735 (grind)	1020, 2345 SAE
5565		Sliding gear hub hole	3.862	3.860 (grind)	2320, 3320, 2345, 3350 SAE
5593	1	Reverse idler gear shaft	1.247	1.246 (grind)	2320 SAE
5592		Reverse idler gear bush.—bore	1.251	1.250 (ream)	26 SAE
5571	3	Trans. shift fork bore	.861	.860 (ream)	1025, 1035 SAE
5578		Trans. shift fork rod	.8595	.8585 (grind)	1020, 1010 SAE
7037	3	Trans. front hanger—bore	6.006	6.004	
5511		Trans. front trunnion	6.000	5.998	

GEAR DATA

Part No.	Fit No.	PART			MATERIAL
5511		Gear case centers	6.004	6.000	
5565		First gear maximum pitch diam.	8.780		
5565		First gear minimum pitch diam.	8.798		
5534		Countershaft gear max. pitch d.	3.198		
		Countershaft gear min. pitch d.	3.184		
5534		Add other gears			

STEERING GEAR

Part No.	Fit No.	PART			MATERIAL
7529		Jacket bushing—upper	1.872	1.871 (tin and sweat in place)	26 SAE
7577		Jacket tube	1.875	1.873 (ream-steel tube)	16 B. W. G. (.065)
7526	1	Upper housing cap bushing	1.877	1.876	26 SAE
7508		Upper housing cap bore	1.875	1.873 (ream)	Malleable iron
7531	1	Pedal shaft bushing	1.253	1.251	26 SAE
7508		Pedal shaft bushing bore in cap	1.250	1.248 (ream)	Malleable iron
7526	1	Steering column shaft bush. O. D.	2.3145	2.3135	26 SAE
		Housing bore—column bushing	2.3125	2.3105	Malleable iron
7510	2	Steering column shaft	1.468	1.466 (grind) 3/8 inch wall	Seamless steel tube
7529		Jacket bushing—upper	1.471	1.469 (ream)	26 SAE
7510	3	Steering column shaft	1.479	1.477 (grind) 3/8 in. wall	Seamless steel tube
7525		Steering column coupling	1.482	1.480 (ream)	DFS—malleable iron
7508	3	Upper housing cap	2.9985	2.996	Malleable iron
7504		Main housing bore	3.000	2.9985 (ream)	Malleable iron
7506	2	Worm shaft	1.5145	1.5135 (grind)	1020 SAE
7526		Upper housing cap bushing bore	1.516	1.515 (line ream)	26 SAE
7656	2	Pedal shaft	1.000	.998	CRS
7531		Pedal shaft bushing bore	1.003	1.001 (line ream)	26 SAE
7509	3	Steering gear housing cover (pr.)	6.124	6.122	Malleable iron
7504		Steering gear housing bore	6.125	6.123	Malleable iron
7505	2	Worm wheel shaft	1.996	1.997 (grind)	1020 SAE
7554		Worm wheel bushings bore	1.999	2.000 (ream in place)	26 SAE
7523	2	Spark tube bushing O. D.	.380	.378	Brass tubing
7521		Spark tube bore	.375	.374 (ream)	16 BWG steel tube
7522	2	Throttle rod	.3135	.3115	CRS
7523		Spark tube bushing bore	.316	.315 (ream after press)	Brass tubing
7521	2	Spark tube	.505	.495	Steel tubing
7515		Sector bracket	.510	.505 (ream)	Malleable iron
7505		Worm gear thickness	1.625	1.622	
7544	2	Washers thickness	187	.185	
7504		Steering gear depth housing	2 000	1.995	

Clearance with low limit case high limit gears = .002 tight.
Clearance with high limit case and low limit gears = 0105 loose

REAR AXLE

Part No.	Fit No.	PARTS			MATERIAL
6204	1	Housing sleeve (print dim.)	4.131	4.129 (selective fit)	3130 SAE
6202		Housing—bore (print dim.)	4.132	4.130 (15 ton pressure)	Cast steel
6204	3	Housing sleeve	4.131	4.129	3130 SAE
6249		Brake anchor—bore	4.132	4.130	1020 or cast steel
6204	3	Housing sleeve	4.123	4.124 (grind)	3130 SAE
6218		Housing sleeve bearing (roller)	4.125	4.126	
6281	3	Axle shaft spline—top of keys	2.988	2.978 (driving flange was shrunk on the axle shaft)	3140 SAE
6282		Axle shaft drive flange—bottom of keyway	3.000	2.998	3130 SAE
6281	3	Axle shaft spline—bottom	2.576	2.573	3140 SAE
6282		Drive flange top of keys	2.571	2.568	3130 SAE
6281	4	Axle shaft spline key—width	.466	.464	3140 SAE
6282		Drive flange keyway—width	.464	.462	3130 SAE
6222	3	Worm gear bore—spline top	11.650	11.645 (generated)	See page 1316
6325		Differential case tongue side—spline bottom	11 631	11.622 (generated)	1020 or steel casting
6222	3	Worm gear bore—spline bottom	11.786	11.769 (generated)	See page 1316
6325		Differential case tongue side—spline top	11 758	11.755 (generated)	1020 or steel casting
6326	3	Diff. case recess side counterbore	10.376	10.375	1020 or steel casting
6325		Diff. case tongue side fit in counterbore	10.276	10.375	1020 or steel casting
6326	1	Differential case recess side fit in counterbore	11 768	11.766	1020 or steel casting
6222		Worm gear counterbore	11 766	11.764	See page 1316
6326		Differential case recess side width to shoulder	7443	.7243	1020 or steel casting
6325		Differential case tongue side width	.752	.750	1020 or steel casting
6222		Worm gear hub thickness	1.503	1.500	See page 1316
6328		Differential side gears and washers assembled in case	5 490	5.456	Make allowance of plus or minus for pinch fit of cases on gear.
6325 6326		Dist. between faces in case	5.508	5.504	
6330	3	Differential spider pin diameter	1.375	1.373 (grind)	2315 SAE
6325		Spider pin hole in housing	1.376	1.375	1020 or steel casting
6330	2	Differential spider pin diameter	1 375	1 373 (grind)	2315 SAE
6329		Differential pinion—bore	1 379	1 377 (grind)	2315 SAE
6330	2	Differential spider bore	4 255	4 253 (grind)	2315 SAE
6328		Differential side gear hub	4 249	4 247 (grind)	2315 SAE
6224	3	Worm shaft diameter	2 5635	2 5630 (grind)	3120 SAE
6556		Worm shaft bearing diameter	2 5630	2 5640	
6281	3	Axle shaft differential end—spline top	2 988	2 978 (grind)	3140 SAE
6328		Side gear splines—bottom	3.005	2.995 (broached)	2315 SAE
6281	3	Axle shaft differential end—spline bottom	2 576	2 573	3140 SAE
6328		Side gear spline—key tops	2,581	2.579 (grind)	2315 SAE
6281	2	Axle shaft differential end—key width	.466	.464	3140 SAE
6328		Side gear keyway—width	.471	.467	2315 SAE
6203	3	Worm gear carrier step	15 995	15.998	Malleable iron
6202		Axle housing bore	16.000	15.994	Cast or pressed steel
6263	1	Brake anchor pin (press)	1.127	1 126 (turn)	3120 SAE
6248		Brake anchor pin hole	1.125	1.124 (ream)	1025 or cast steel
6202	3	Rear axle housing flange	9.252	9.249	Cast or pressed steel
6248		Brake anchor casting recess	9.257	9.253	1025 or cast steel
6536	3	Rear wheel hub	7.998	7.992	Malleable iron
6539		Rear wheel hub flange bore	8.004	8.000	Cast steel
6282	3	Rear axle shaft drive plate	9 250	9.245	3130 SAE
6539		Rear wheel hub flange—recess	9.257	9.252	Cast stee
6251	2	Brake shaft	1.252	1.248	1020 SAE
6250		Brake shaft bushing—bore	1.262	1.259 (ream in place)	26 SAE
6251		Brakeshaft theoretical top of serration	1.219	1.209	1020 SAE
6251		Brakeshaft theoretical bottom of serration	1.141	1.131	1020 SAE
6251		Brakeshaft serration top	1 203	1.205	1020 SAE
6251		Brakeshaft serration bottom	1 145	1.147	
6251		Angle of serrations	9 degrees		
6374		Lever theoretical top of serration	1.143	1.141	1035 SAE
6374		Lever theoretical bottom of serration	1.221	1.219	1035 SAE
6374		Lever serration top	1.153	1.151	1035 SAE
6374		Lever serration bottom	1 211	1.209	1035 SAE
6374		Angle of serrations	9 degrees		
6250	1	Brake shaft bushing (press)	1.502	1.501	26 SAE
6263		Brake shaft bushing bore in brake anchor	[illegible]	1.497	1025 or cast steel

Heat Treatment of Parts

The steel numbers and heat treatments (designated by letter) used in the following table refer to the Society of Automotive Engineers Steel Specifications, except in the case of steel No. 1040, which is a special steel for propeller shaft parts and has a carbon content of 0.35 to 0.45 per cent with 0.40 per cent desired. Otherwise the composition of steel 1040 is the same as that of No. 1035 S. A. E. steel. Full information regarding S. A. E. steels and heat treatments is given in Vol. 1, S. A. E. Handbook.

Part No.	Part Name	Requirements on Drawings: Steel No.	Hardness: Brin.	Hardness: Scler.	Heat Treatment	Revised Requirements
1005-V	Stud, cyl. head	3130			Heat 1575. Quench. Reheat-1000. Cool slowly	32-40 scle. SAE ht. "H"
1010-V	Valve	3140		40 min.	Harden	40-50 scle. SAE ht. "H"
1024-V	Bolt, main brg.	3130			Heat treat	32-40 scle. SAE ht. "H"
1025-V	Stud, front main brg.	3130			Quench and draw	32-40 scle. SAE ht. "H"
1026-V	Nut, conn. rod bolt	3130			Heat treat	None
1028-V	Stud, cyl. hold down	3130			Heat treat	32-40 scle. SAE ht. "H"
1065-X	Conn. rod	1035		35-40	SAE ht. "D"	32-40 scle. SAE ht. "H"
1066-V	Belt, conn. rod	3130			Heat treat	32-40 scle. SAE ht. "H"
1075-V	Piston-pin	1020	470	70-80	Carb. 1/16 in.	SAE ht. B (Carb. 1/16-3/64)
1079-V	Tappet, valve	1114		75 min.	Case harden	75-80 scle. carb. 3/64-1/16
1080-V	Roller, valve tapp.	1020		80 min.	Case hard 1/16	80-90 scl. SAE ht. "B" (carb. 1/16-3/64)
1081-V	Pin. valve tapp. roll	DR. PD		70-80	Harden	80-90 scle. SAE ht. "B"
1082-V	Adj. screw, valve tapp.	Per bar		75 min.	Case harden	(Carb. 3/64-1/16) threads soft
1083-V	Lock nut, valve tapp.	1114			None	None
1089-V	Dr. gear, oil pump	1114			Case hard. 1/64-1/64	Use SAE 1020 scle. 70-80 SAE ht. "B" carb. 1/64-3/32
1093-Y	Crankshaft	1045		38-42	SAE, ht. "H"	38-45 scle. SAE ht. "H"
1095-V	Bolt, flywheel	3130			Heat treat	32-40 scle. SAE ht. "H"
1099-Y	Camshaft	1020		65-70	Case harden	SAE ht. "B" (Carb. 3/64-1/16) 65-70 scle. on cams and bearings
1101-V	Gear, oil pump drr.	1020		70 min.	Case hard 1/16-3/32	70-80 scle. SAE "B" (Carb. 3/64-1/16)
1120-V1	Gear, oil pump drr.	3130			Ht. tr. bar	32-40 scle. SAE ht. "H"
1123-V	Stud, oil pump idlr.	CRS			Case harden	None
1126*-W	Gear, crankshaft	1035			Heat treat	32-40 scle. SAE ht. "H"
1127*-W	Gear, pump and mag.	1035			Heat treat	32-40 scle. SAE ht. "H"
1131-W	Shaft, idle gear	1020		75 min.	Case harden	Use SAE 1045. 40-50 scle. SAE ht. "A"
1134-W	Shaft, generator	1045		40-45	SAE ht. "H"	None
1146-V	Disk, governor	Stpg.			Carb. 1/32-1/16	None
1160-V	Adj. screw, gover.	CRS		50-60	Case harden	Carbon end to produce hardness
1208-V	Nut, plain	1114			None	None

Part No.	Part Name	Requirements on Drawings: Steel No.	Hardness: Brin.	Hardness: Scler.	Heat Treatment	Revised Requirements
1304-V	Washer, gov. thr. brg.	1020		80 min.	Case hard. 1/32-3/64 SAE ht. "H"	5-85 scle. SAE ht. "B" (carb. 3/64-1/16)
1484-X	Lever, gear shif.	1025			Draw at 1000	None
1495-V	Bolt, clutch spr.	3130		33-38	SAE ht. "H"	None
1572-W	Clip, rear spr.	2320		45-50	SAE ht. "H"	None
1573-W	Clip, front spr.	2320		45-50	None	None
1612-X	Ring, worm gear					
	Retaining	1035		32 min.	SAE ht. "H"	None
1613-W	Lever, brake	1035	200-220		Heat 1510-1530	1-heat to 1600, 1b. 20m.
					Quench in oil	Quench in water
					Draw at 850-900	3—draw at 950, 1b. 20m.
2326-X	Yoke, prop. shaft Sleeve (front)	1040		35-44	SAE ht. "P" cool slowly	1. Heat 1525 plus or minus 10 2. Reht. 1425 plus or minus 10 Quench in oil. 4. Draw to hardness
2327-V	Shaft, prop, shaft stub	1040		70-90 on splines 40-50 on neck and shoulder	Heat 1425 plus or min. 10 Quench splined end in water; whole piece in oil.	None
2328-W	Yoke, prop. shaft plain (front)	1040 L		30-40	Heat 1525 plus or min. 10 Cool slowly. Reheat 1425 plus or minus 10. Quench in oil. Draw to hardness.	None
2330-V	Flange, prop. shaft, compan. (front)	1040		35-44	SAE ht. "P"	1. Heat 1525 plus or minus 10. 2. Cool slowly. 3. Quench in oil. 4. Draw to hardness
2331-X	Yoke, prop. shaft, flange (front)	1040		35-44	SAE ht. "P"	1. Heat 1525 plus or minus 10 2. Cool slowly. 3. Quench in oil. 4. Draw to hardness
2333-V	Journal, prop. shaft (front)	1020		70 min.	Carb. at 1650 plus or minus 10. Cool in box. Ht. to 1575 plus or minus 10. Quench in oil. Reht. to 1425 plus or minus 10. Quench in water.	None
2338-V	Bolt, prop. shaft flange (front)				Heat to 1525 plus or minus 10. Quench in oil. Ht. to 1350 plus or minus 10. Quench in oil. Ht. to 750 plus or minus 10. Cool slowly	None
2344-X	Yoke, prop. shaft sleeve (rear)	1040		35-44	SAE ht. "P"	1. Heat 1525 plus or minus 10. 2. Cool slowly. 3. Quench in oil. 4. Draw to hardness
2345-X	Yoke, prop. shaft plain (rear)	1040		30-40	Ht. 1525 plus or minus 10. Cool slowly. Ht. to 1425 plus or minus 10. Quench in oil. Draw	None
2351-V	Journal, prop. shaft (rear)	1020		70 min.	Carb. at 1650 plus or minus 10. Cool in box. Ht. to 1575 plus or minus 10. Quench in oil. Heat to 1425 plus or minus 10. Quench in water.	None

Heat Treatment of Parts—Continued

Part No.	Part Name	Requirements on Drawings				Revised Requirements
		Steel No.	Hardness		Heat Treatment	
			Brin.	Scler.		
	Bushing, prop. shaft journal (rear)	1020		70 min.	Carb. at 1650 plus or minus 10. Cool in box. Ht. to 1575 plus or minus 10. Quench in oil. Ht. to 1425 plus or minus 10. Quench in water	None
2353-X	Yoke, prop. shaft flange (rear)	10:0		35-44	SAE ht. "P"	1. Heat at 1525 plus or minus 10. 2. Cool slowly. 3. Heat to 1425 plus or minus 10. 4. Quench in oil. 5. Draw
2354-V	Flange, prop. shaft compan. (rear)	1040		35-44	SAE ht. "P"	None
2355-V	Shaft, prop. shaft stub (rear)	1040		70-90 on splines 40-50 on neck and shoulder	Heat 1425 plus or minus 10. Quench splined end in water. Whole piece in oil	None
2305-W	Cran'. starting	1025			SAE bt. "H"	None
2512-V	Jaw, st'rtg. crank	1020		50 min.	Carb. jaws 1/32-1/64	None
K2816-V	Screw, hex. head	1114			None	None
3306-V	Gage, valve tappet	Tool steel			Tempered	None
3508-V	Spindle, fan	3130			Ht. tr. bar	32-40 scle. SAE ht. "H"
4081-V	Cam, generator clutch	2320			Carb. harden, grind	None
4082-V	Shell, generator clutch	1010			Carb. harden, grind	None
4083-V	Plate, generator clutch	Sheet steel			Case harden	None
4085-V	Roll, generator clutch	2320		80 min.	Heat treat	None
4086-V	Plunger, generator clutch	2320			Heat treat	
4039-V	Disk, gen. clutch	C. R. S.			Carb. and harden	None
4279-V	Cam, distributor	C. D. S.		70 min.	Carb. 1/32-1/64 and harden	None
4281-V	Screw, dist. cam.	C. D. S.			Cyn. for 5 min. Quench in water	None
4282-V	Bushing, distr. cam screw	C. D. S.			Cyn. for 5 min. Quench in water	None
4285-V	Lock nut, distr. cont. screw	1114			Case harden, zinc plate	None
4298-V	Shaft, distributor	C. D. S.		70 min.	Carb. 1/32-1/64 and harden	None
5015-W	Shaft, clutch	6120		75-85	Carb. 1/32, double quench	1. Pack threads. 2. Carb. 1/32 at 1650. 3. Cool slowly in carbonising material. 4. Ht. at 1550 15 min. 5. Quench in oil. 6. Anneal and cut keyways. 7. Reht. at 1380-1400 30 min. 8. Quench in oil. 9. Draw at 375 20 min.
5041-X	Yoke, release	1025			Carb. 1/32, harden ball ends	1. Carb. 1/32 at 1650. 2. Cool slowly in carbonising material. 3. Ht. at 1550, 15 min. 4. Quench in oil 5. Anneal all over at 1150. 6. Reht. in lead at 1400, 4 min. 7. Quench in water
5042-V	Screw, trunnion	C. R. S.		70 min.	Carb. 1/64-1/32	None
5043-V	Socket, clutch rel. yoke	C. R. S.		70 min.	Carb. 1/64-1/32	1. Carb. 1/64-1/32 at 1650. 2. Reheat in gas furnace at 1420, 12 min. 3. Quench in oil. 4. Draw in oil at 350, 10 min.
5045-V	Bushing, clutch rel. lever	C. R. S.			Cyanide, harden	1. Ht. in cyanide 8 min. 2. Quench in water
5047-V	Bushing, rel. rocker sht. eye	C. R. S.			Cyanide	1. Ht. 8 min. Cyanide. 2. Quench in water
5252-WS	Latch and rod rev.	C. R. S.		70 min.	Carb. 1/64 min.	1. Carb. 1/32 at 1650, 7 hr. 2. Reheat at 1420, 4 min. 3. Quench in oil. 4. Draw at 325, 10 min.
5253-WS	Latch lever brake	C. R. S.		70 min.	Carb. 1/64 min.	1. Carb. 1/64-1/32 at 1650 for 8 hrs. 2. Reheat at 1420 in lead on end. 3. Quench in oil. 4. Draw at 325, 10 min.
5263-V	Interlock	1020			Case harden	1. Carb. 1/32 at 1650. 2. Reheat in gas furnace at 1400, 10 min. 3. Quench in oil. 4. Draw at 325, 20 min.
5264-V	Pin, inter. guide	C. R. S.			Cyanide	1. Heat in cyanide at 1400, 10 min. 2. Quench in water
5265-X	Lever, gear shift hand	1025			SAE ht. "H". Draw at 1000	None
5270-V	Nut, spoon hinge	Iron or st'l			Cyanide, harden	1. Heat in cyanide at 1400, 8 min. 2. Quench in oil.
5271-V	Latch, reverse	C. R. S.		70 min.	Carb. 1/64 min.	1. Carb. 1/64-1/32 at 1650, 7 hr. 2. Reheat in lead at 1400, 4 min. 3. Quench in oil. 4. Draw at 325, 10 min.
5283-W	Lever, shifting first and second speed	1025		30 min.	SAE ht. "H"	None
5284-W	Lever, shifting third and fourth speed	1025		30 min.	SAE ht. "H"	None
5285-W	Lever shifting reverse	1025		30 min.	SAE ht. "H"	None
5301-X	Lever, brake	1025		30-43	SAE ht. "H"	None
5307-V	Slide, brake lever	C. R. S.			Cyanide, harden	1. heat in cyanide at 1400, 10 min. 2. Quench in oil
5303-V	Sector, brake	C. R. S.			Harden not less than 1/32	1. Carb. 1/32-1/64 at 1650, 7 hr. 2. Reheat at 1410-1420, 12 min. 3. Quench in oil. 4. Draw at 375, 20 min.
5311-V	Latch, brake	C. R. S.		70 min.	Carb. 1/64 min.	1. Carb. 1/32 at 1650, 7 hr. 2. Reheat on end in lead, 4 min. 3. Quench in oil. 4. Draw at 350, 10 min.
K5451-V	Screw, hex. head	1114			None	None
5439-V	Pin, yoke	C. R. S.		70 min.	Carb. and harden 1/32-1/64 min.	1. Carb. 1/32 at 1650, 7 hr. 2. Reheat in gas furnace at 1400, 10 min. 3. Quench in oil. 4. Draw at 350, 10 min.
5517-W	Gear, main drive	2320		80-90	Carb. 1/32-1/64	1. Carb. 1/32-1/64 at 1650, 11 hr. (Pack threads here). 2. Heat all over in sq. gas furnace at 1550, 30 min. 3. Quench in oil. 4. Reheat in lead at 1380-1400, 6 min. 5. Quench in oil. 6. Draw shank in lead at 1380. Draw all over at 357, 30 min.

5531-W	Gear, countershaft	2320	3-3.3 (340-418)	80-90	SAE ht. "G". carb. 3/64-1/16	None
5532-W	Gear, third speed (countershaft)	2320	(340-418) 3-3.3	80-90	SAE ht. "G"	1. Carb. 1/32-3/64 at 1650, 11 hr. 2. Heat at 1550, 6 min. 3. Quench in oil. 4. Reheat in lead at 1330-1400, 6 min. 5. Quench in oil. 6. Draw in oil at 357, 30 min.
5533-W	Countershaft gear, second speed	2320	(340-418) 3-3.3	80-90	Carb. 3/64-1/16 SAE ht. "G"	None
5534-X	Countershaft	2345		72-78 on gear shank	SAE ht. "H"	1. Carb. 1/32-3/64 at 1650, 11 hr. 2. Heat at 1550, 15 min. 3. Quench in oil. 4. Reheat at 1380-1400. 5. Quench in oil. 6. Draw all over at 375, 30 min. 7. Anneal threads in lead
5551-W	Shaft, main	2320		80-90 on spline 40-50 elsewhere	SAE ht. "G". carb. 3/64-1/16	1. Carb. 1/32 at 1650, 11 hr. (Pack threads here). 2. Heat all over at 1550, 35 min. 3. Quench in oil. (Anneal end and cut keyway here). 4. Reheat at 1400, 30 min. 5. Quench in oil. 6. Draw taper at 375
5552-W	Second and fourth speed sliding gear	2320	(340-418) 3-3.3		Carb. 3/64-1/16 SAE ht. "G"	None
5563-W	Hub, first and second speed sliding gear	1020		75-85	Carb. 3/64-1/16	None
5564-W	Gear, second speed sliding	2320	3-3.3 (340-418)	80-90	SAE ht. "G", carb. 3/64-1/16	None
5565-W	Gear, first speed sliding	2320	3-3.3 (340-418)	80-90	SAE ht. "G", carb. 3/64-1/16	1. Carb. 1/32 at 1650, 9 hr. 2. Heat in lead at 1550, 6 min. 3. Quench in oil. 4. Reheat in lead at 1380 to 1400, 6 min. 5. Quench in oil. 6. Draw at 375, 30 min.
5572-W	Fork, rev. shift	1025		30 min.	SAE ht. "H"	None
5573-V	Screw, shift for lock	1020			Carb. 3/64-1/16	None
5576-W	Shifter rod third and fourth speed	1025		75-85	Case harden 3/64-1/16	1. Carb. 1/32 at 1650, 8 hr. 2. Reheat at 1400-1410. 3. Quench in water. Note: Harden above notched only
5577-W	Shifter rod, first and second speed	1025		75-85	Case harden 3/64-1/16	1. Carb. 1/32 at 1650, 8 hr. 2. Reheat at 1400-1410. 3. Quench in water. Note: harden above notches only
5578-W	Shifter rod reverse	1025		75-85	Case harden 3/64-1/16	1. Carb. 1/32 at 1650, 8 hr. 2. Reheat at 1400-1410. 3. Quench in water. Note: harden above notches only
5579-V	Rod—end, shift	1025			Cyanide, harden head only	1. Carb. in cyanide at 1400, 20 min. 2. Quench in water. Note: harden head end only
5583-V	Poppet	1010		60-70	Carb. 1/32 harden	1. Clay pack holes. 2. Carbonize at 1500, 8½ hrs. 3. Cool slowly in carbonizing material. 4. Quench in oil from pots
5591-W	Gear, reverse idler	2320	3-3.3 (340-418)	80-90	Carb. 3/64-1/16. SAE ht. "G"	1. Carb. at 1650, 10 hr. 2. Cool slowly in carbonizing material. 3. Heat in lead at 1550, 15 min. 4. Quench in oil. 5. Reheat in lead at 1380-1400 15 min. 6. Quench in oil. 7. Draw at 375, 30 min.
5593-V	Shaft, reverse idler, gear	2320		75-85	Carb. not less than 1/32. SAE ht. "G"	1. Carb. 3/64-1/16 at 1650, 9 hr. 2. Heat in sq. furnace at 1550, 30 min. 3. Quench in oil. 4. Reheat in sq. furnace at 1370-1380. 5. Quench in water and oil. 6. Draw head to red in lead. Draw all over at 350, 30 min.
K5650-V	Rivet, button head	Soft steel			None	None
5651-X	Countershaft, extended end	2320	3-3.3 (340-418)	80-90	SAE "G", carb. 3/64-1/16	None

K5751-V	Screw, hex. head	1114			None	None

Heat Treatment of Parts—Continued

Part No.	Part Name	Requirements on Drawings				Revised Requirements
		Steel No.	Hardness		Heat Treatment	
			Brin.	Scler.		
6003-V	Bushing, strg. knuckle pin (center)	1020			Carb. and harden	1. Carb. at 1600, 12 hr. 2. Cool slowly in carbonizing mixture. 3. Reht. to 1400, 40-50 min. 4. Quench in water
6005-Y	Knuckle, steering (R. H.)	3130		32-36	Heat 1535-1565. Quench in oil. Draw 1100-1150	1. Anneal before machining at 1550, 2 hr. 2. Heat at 1550, 2 hr. 3. Quench in oil. 4. Draw at 1100, 2 hr.
6006-V	Bushing, strg. pin (in knuckle)	1020			Carb. and harden	1. Carb. $\frac{1}{32}$ at 1650, 12 hr. 2. Cool slowly in carbonizing material. 3. Reht. at 1400, 40-50 min. 4. Quench in water
6009-Y	Knuckle, strg. (L. H.)	3130		32-36	Heat 1535-1565. Quench in oil. Draw 1100-1150.	1. Anneal before machining at 1550, 2 hr. 2. Heat at 1550, 2 hr. 3. Quench in oil. 4. Draw at 1100, 2 hr.
6010-V	Nut, spindle (R. H.)	1020			Cyanide	1. Carb. in cyanide. 2. Quench in water
6011-V	Pin, outer brg. adj. nut	1114			None	None
6013-V	Adj. nut, outer brg. front axle spindle	1020			Cyanide	1. Carb. in cyanide. 2. Quench in water
6014-V	Jam nut, outer bearing (R. H.)	1020			Cyanide	1. Carb. in cyanide. 2. Quench in water
6015-V	Jam nut, outer spindle nut (L. H.)	1020			Cyanide	1. Carb. in cyanide. 2. Quench in water
6016-V	Lock nut, spindle steel stpg.				None	None
6017-V	Pin, strg. knuckle	1020			Carb. $\frac{1}{32}$, harden	75-85 scle. 1. Carb. $\frac{1}{32}$ at 1700, 12 hr. 2. Quench from pot in water
6018-V	Key, strg. knkle. pin	3130			Heat treat	32-40 scle. 1. Heat at 1500. 2. Quench in water. 3. Draw at 1000
6019-V	Washer, strg. knkle. spacing (thin)	1020			Carb. harden	1. Carb. $\frac{1}{32}$ at 1700, 11-12 hr. 2. Cool in carbonizing material. 3. Heat to 1400-1425, 40 min. 4. Quench in oil
6022-V	Washer, knkle thrt.	1020			Carb. $\frac{1}{32}$, harden	File hard. 75-85 scle. 1. Carb. $\frac{1}{32}$ at 1700, 18 hr. 2. Cool with pot. 3. Reheat at 1400, 49 min. 4. Quench in water
6029-Y	Arm, steering (L. H.)	3130		32-36	Heat 1535-1565. Quench in oil. Draw 1100-1150	1. Heat at 1500, 1 hr. 40 min. 2. Quench in oil. 3. Draw at 1100-1150, 2 hr.
6030-X	Arm, steering (R. H.)	3130		32-36	Heat 1535-1565. Quench in oil. Draw 1100-1150	1. Heat at 1500, 1 hr. 40 min. 2. Quench in oil. 3. Draw at 1100-1150, 2 hr.
6031-V	Key, steering arm	Tool steel			Draw to 400-450	1. Heat at 1500, 40 min. 2. Quench in oil. 3. Draw at 800, 30 min.
6032-V	Ball, strg. arm	3120		75 min.	Carb. $\frac{1}{32}$, harden ball	1. Carb. $\frac{1}{32}$ at 1700, 8 hr. 2. Dip from pot in oil. 3. Heat at 1550, 50-60 min. 4. Quench in water. 5. Heat at 1400, 1 hr. 20 min. 6. Quench [illegible] ball in water. 7. Draw shank in lead, one at a time
6033-W	Rod, strg. cross	1020			None	None

Part No.	Part Name	Requirements on Drawings				Revised Requirements
		Steel No.	Hardness		Heat Treatment	
			Brin.	Scler.		
6035-X	Rod—end, cross	1025			Anneal	1. Heat at 1600 for 3 hr. 2. Cool in air
6036-V	Bushing, strg. cross rod—end	1020		75 min.	Carb. $\frac{1}{32}$, harden	1. Carb. $\frac{1}{32}$, 10-11 hr. 2. Dip from pot in water. 3. Heat at 1400, 40 min. 4. Quench in water
6037-V	Bushing, lower steering rod—end pin	1020		75 min.	Carb. $\frac{1}{32}$, harden	1. Carb. $\frac{1}{32}$, 10-11 hr. 2. Dip from pot in water. 3. Heat at 1400, 40 min. 4. Quench in water
6038-V	Pin, strg. rod—end	1020		75 min. after grinding	Carb. $\frac{1}{32}$. harden	1. Carb. $\frac{1}{32}$ at 1700, 10 hr. 2. Dip from pot in water. 3. Reheat at 1400, 50 min. 4. Quench in water
6041-V	Key, strg. cross rod—end pin	3130			Heat treated stock	32-40 scle. 1. Heat at 1500. 2. Quench in water. 3. Draw at 1000
4043-W	Spring seat, fr. axle	1025			None	None
6054-V	Spacer, hub bearing	1025			None	None
6059-V	Washer, knuckle spacing (medium)	1020			Carb., harden	1. Carb. $\frac{1}{32}$ at 1700, 11-12 hr. 2. Cool in carbonizing material. 3. Heat at 1400-1425, 40 min. 4. Quench in oil
6066-V	Washer, knuckle spacing (thick)	1020			Carb., harden	1. Carb. $\frac{1}{32}$ at 1700, 11-12 hr. 2. Cool in carbonizing material. 3. Heat at 1400-1425, 40 min. 4. Quench in oil
6067-V	Nut, strg. arm	1114			None	None
K6068-V	Screw, hex. head	1114			None	None
6155-V	Plunger, reach rod	1010		75 min.	Case harden [illegible]	None
6157-V	Plug, reach rod	1114			Cyanide in bath, harden	None
6204-W	Sleeve, housing (R. H.)	3130		31-34	Heat 1530-1565. Quench in oil. Draw 1200-1300	1. Heat at 1500, 2 hr. 2. Quench in oil. 3. Draw at 1150-1225, 2 hr.
6205-V	Sleeve, housing (L. H.)	3130		31-34	Heat 1530-1565. Quench in oil. Draw 1200-1300	1. Heat at 1500, 2 hr. 2. Quench in oil. 3. Draw at 1150-1225, 2 hr.
6206-V	Screw, housing sleeve retaining	1114		None	None	None
6211-W	Stud, diff. brg. cap	3130		32-36	Heat 1535-1565. Quench in oil. Draw 1100-1500	1. Heat at 1550, 1 hr. 2. Quench in oil. 3. Draw at 1100, 1 hr.
6224-X	Shaft, worm	3130		70-85 thread end	On whole shaft. Carb. $\frac{1}{32}$, heat to 1550, quench and draw to 700	1. Carb. $\frac{1}{32}$ at 1650, 12 hr. 2. Quench from pot in oil. 3. Reheat at 1550, 2 hr. 4. Quench in water. 5. Draw threads in lead at 1400. 6. Draw taper at 850. 7. Draw in oil at 350
K6223-V	Nut, worm shaft	1114			Cyanide	1. Carb. in cyanide. 2. Quench in water
6233-V	Bolt, worm shaft forward bearing	3120	205-240		SAE ht. "H"	1. Heat at 1500, 4-40 min. 2. Quench in oil. 3. Draw at 900, 30 min.
6210-W	Adj. nut wheel brg. (R. H.)	1025			Cyanide 30 min	1. Carb. in cyanide, 30 min. 2. Quench in water
6242-W	Adj. nut, wheel brg. (L. H.)	1025			Cyanide 30 min	1. Carb. in cyanide, 30 min. 2. Quench in water
6243-W	Jam nut, axle brg. (R. H.)	1025			Cyanide 30 min.	1. Carb. in cyanide, 30 min. 2. Quench in water

6244-W	Jam nut, axle brg. (L. H.)	1025			Cyanide 30 min.	1. Carb. in cyanide, 30 min. 2. Quench in water
6245-W	Lock washer, axle al've brg. adj. nut	Steel stpg.			None	None
6249-X	Anchor, brake (R. H.)	1025			None	None
6251-V	Shaft, brake	1020			None	None
6254-V	Spacer, hub brg.	1020			None	None

Fits, Tolerances and Heat Treatments Applied in Production

(*Continued from page* 1316)

Front Axle and Steering Gear—The front axle is of I-beam design with Elliott type steering knuckles fitted with taper roller bearings in the wheels only. The king pins are held fast in the knuckles and turn in bushings fitted in the axle yoke. The steering gear is of the conventional fore and aft worm and gear type, fitted with ball thrust bearings, the gear having a full circumference and the spark and throttle control being on the outside.

Clutch—The clutch is of the dry multiple disk type and has 19 plates, of which 9 are faced with woven asbestos fabric. The clutch is enclosed by a bell-housing bolted to the crankcase.

Universal joints are of the yoke and cross type and are enclosed in a pressed steel casing. The propeller shaft ends are splined and welded into the tubular propeller shaft.

Rear axle is of full floating type with the worm gearing, the differential being of the bevel gear type with four pinions. Taper roller bearings are used. The axle shafts are splined on both ends, one end sliding into the splined differential gear and the other end shrunk into the driving flange. The worm gear is provided with splines cut on the inner circumference and fits over the differential case, which is also splined. This construction is employed to relieve the bolts which clamp the worm gear to the differential case from shearing strain.

A RESOLUTION has been moved in the British House of Commons to give protection to certain "key" industries, the maintenance of which on a definite scale of magnitude is regarded as being in the national interests. The list of industries includes magnetos, metallic tungsten, ferro-tungsten, and manufactured products of metallic tungsten, and compounds of thorium, cerium, and the other rare earth metals, and all synthetic organic chemicals. The proposal is that on all these articles an ad valorem duty of 33⅓ per cent shall be imposed. A similar duty should, it is suggested, be placed upon other articles which may be offered for sale in the United Kingdom at prices below the cost of production or at prices which by reason of the condition of currency are below the prices at which similar goods could be profitably manufactured in the United Kingdom.

IN planning the Forum department for the Engineering Number of AUTOMOTIVE INDUSTRIES, a goodly number of engineers were asked to contribute. In each case a question was suggested, but it was made plain to the engineer that his most advanced thought was requested. As was the desire in the planning, a number of the contributors have entirely ignored the question sent to them, and have written the thought uppermost in their minds.

The Engineering Staff of AUTOMOTIVE INDUSTRIES believes that this presentation of engineering opinion is unique for this field of thought. Our hope is that the discussion will not end here. The Forum is—as it always has been—open to the thought in the industry. Further discussion of the points presented here—or others the reader may have in his mind—is invited. Such a discussion, whether it is a presentation of opinions or the asking of questions, is the most profitable kind of co-operation. The door is open to each reader.

We invite you to participate in the feast of divergent opinion we have prepared with the help of the automotive community:

The Next Step in Engine Design

Elimination of Throttling Under Light Loads

Editor, AUTOMOTIVE INDUSTRIES:

In my opinion the most logical step in rendering automobile engines more efficient under average working conditions is to eliminate throttling and low compression under light loads, just as was done with steam engines during the development of that industry.

History will repeat itself. For seventy years steam engines rejected the steam at boiler pressure, then Watt introduced complete expansion and, with a few other minor improvements, obtained four times the power per pound of coal.

For twenty-five years automobile engines have been releasing the burning gases of the working stroke at less volume than was compressed, rejecting more than 40 per cent of the heat units to the exhaust.

For over 100 years steam engines were governed by throttling the intake with a butterfly valve, reducing the initial pressure and efficiency with the load.

Ever since the birth of the automobile engine, always too large for the average load, its output has been controlled by the braking effect of throttling the intake, thereby lowering the compression and the thermal efficiency.

Complete expansion in an internal combustion automobile engine is more practicable than in a steam engine, because we have no cylinder condensation to contend with, yet builders of auto engines have been and are still vying with each other to see which can get the most horsepower per unit of piston displacement when volumetric efficiency has nothing to do with the output per unit of fuel consumed.

As the average working condition of the automobile engine is from one-fifth to one-quarter of its full capacity, it must be designed to give a higher efficiency at these loads.

A complete expansion cycle, developing 30 per cent thermal efficiency at full load, permits of increasing the compression and decreasing the fuel content as the load becomes lighter, thereby eliminating the braking effect of throttling and the thermal losses of low compression.

The automobile industry is in a rut, worn deep by continually following primeval practice of throttling the gases during the induction stroke to control the speed and output, thereby turning into useful work, during the average load, but one gallon of gas for every ten put into the fuel tank.

Such a policy may have been permissible when fuel cost less than maintenance and automobiles were taxed according to their piston displacement.

Now, however, it would be most unwise to design and build engines along the customary and standard lines if better thermal efficiency is desired, and twenty-five years of high volumetric but low thermal efficiency should not be extended or prolonged in this progressive age, especially now that our fuel consumption is approaching nature's supply.

C. E. SARGENT.

Research in Vaporization

Editor, AUTOMOTIVE INDUSTRIES:

Answering your letter, in which you ask the following question: What do you regard as the next logical step in rendering automobile engines more efficient under operating conditions? I would answer as follows:

A proper device for furnishing a thoroughly vaporized mixture to the cylinder at a relatively low temperature and a combustion chamber which will burn this mixture entirely free from knocks at all loads and speeds and with higher compression ratios than possible at present; namely, 4½-1 and above without the use of dopes.

The next step is an engine which will handle any fuel by the use of dopes with high air-cycle efficiency and high combustion efficiency, which, combined, mean high thermal efficiency.

We do not feel a satisfactory vaporization system has yet been produced to furnish a proper mixture to the cylinder with 440 degrees end point fuels under vary-

ing conditions of speed, load and rapidly changing demands of load and speed.

The reason this has not been accomplished is because there has been too little real research and too much experimental development, without the groundwork of true research as a guide.

We expect to attack the problem along this line.

H. L. HORNING,
Waukesha Motor Co.

Refinements in Engine Design

Editor, AUTOMOTIVE INDUSTRIES:

In reply to your question, "What changes in passenger car engine design do you advocate to render these engines more economical under average operating conditions?" one may almost answer "None." Refinements in design, "Yes." Better construction, higher mechanical efficiency, higher compression ratios as soon as the average commercial fuel will permit, and particularly such refinements in design and such care in assembly that the frequency and the cost of overhaul will be reduced at least 50 per cent. By such means maximum brake thermal efficiencies might be increased from the present 20-25 per cent to a possible 30 per cent, and the upkeep cost indefinitely reduced.

However, the most important immediate possibilities of economy involve engine design only indirectly. The major economies which might be realized may be stated as follows:

(a) In unburned fuel (too rich mixtures), aggregating perhaps 25 per cent of the total fuel cost.

(b) Elimination of mechanical losses by the operation of engines at the optimum speed and load. An ideal transmission system (if it existed) could save 15 to 25 per cent of present fuel consumption and perhaps cut in half the cost of upkeep of engines.

(c) A general reduction in weight of cars would reduce the total cost of automobile transportation, now estimated at an average of about 12 cents per car mile, almost in proportion to the reduction in weight. In general, if average cars weighed half as much, the population could afford to use nearly twice as many of them.

These economies cannot be realized if attempted with any sacrifice of comfort and convenience on the part of car users, or with any great increase in complexity of mechanical construction.

(a) Fuel waste is the net result of many causes, chief of which is perhaps the necessity of some sort of manual adjustment of the fuel supply for starting and warming up the engine with the grade of fuel which must be used. The average driver cannot possibly learn to maintain an economical fuel adjustment and, in fact, would not take the trouble even if he knew how (and it takes much trouble with the average car). Unburned fuel will continue to pollute the air until carbureting and manifold systems can be developed which adjust themselves for temperature of the air and the engine, at least as well as present systems do for speed and load, and do it without the care or the interference of the average driver.

(b) The power absorbed in the engine under average driving conditions about equals that required to drive the car. With present types of transmission this cannot be greatly reduced with cars that will satisfy the driver. An ideal transmission should allow the engine to operate always at nearly full load and at a speed which would furnish the power required, adjusting this speed automatically to meet the demands for power. Such a transmission would not only save fuel, but might be much more comfortable to drive, but it does not exist. Why not find a way to solve this problem?

(c) Any reduction of car weight must be accomplished without sacrifice of comfort. The ratio of sprung to unsprung weight and the ratio of car weight to maximum load cannot be reduced without sacrifice of comfort unless spring systems are improved, or other means found to maintain comfortable riding qualities.

H. C. DICKINSON,
Physicist, Bureau of Standards.

The Next Step in Engine Efficiency

Editor, AUTOMOTIVE INDUSTRIES:

In your letter of April 28, you ask me what I regard as the next logical step in rendering automotive engines more efficient under average operating conditions.

My answer would be: Increased compression, or rather expansion, leaner mixtures, and lower friction losses. However, in stating this I am keenly aware that the statement is almost worthless without some words about the way to attain these ends.

Stratification, doping, turbulence, multiple spark plugs, admixture of inert gases, finally the injection principle—all these are means at present being tried out somewhere in the world. The final preponderance of any of these methods will depend as much on the persons backing them as on the value of the methods themselves.

I have reviewed all these things more fully in a bulletin just about to be published by the Engineering Experiment Station of the Ohio State University. To avoid misunderstandings it might be best here to end simply by a reference to this publication.

C. A. NORMAN,
Prof. Machine Design,
Ohio State University.

Trend of Passenger Car Design

Crankcase Dilution and Chassis Lubrication

Editor, AUTOMOTIVE INDUSTRIES:

There are two problems which come to mind that seem to be quite important.

The first is the matter of crankcase dilution, caused by unburned portions of fuel leaking past the pistons and rings and getting into crankcase. This is certainly a big problem, and one which will need solving.

Another problem is to devise a method of properly lubricating chassis parts, such as spring shackles, spring bolts, springs, brake shafts, front axle parts, etc.

At the present time we have the motor, transmission and rear axle worked out to a high degree of perfection from a lubrication standpoint and all out of proportion to the rest of the chassis parts.

Rattles and squeaks are the most frequent cause of cars entering the service station, and this is largely due to the fact that, first, the parts to be lubricated are many in number and often inaccessible, with the result that they do not receive proper attention; second, they are open to the elements, with the result that dirt and water have an opportunity of creeping into the open joints, which is far from a satisfactory lubricating condition.

The writer believes that this problem will be solved, although he is aware of the difficulties to be encountered.

It seems obvious that these parts should be enclosed, so as to exclude dirt, etc., and retain the lubricant and at the same time be lubricated from possibly one or two points accessibly located.

The writer realizes that this is not a new problem, and that various attempts have been made and are being made to solve it. The problem is still with us, and it is an interesting one.

R. S. BEGG,
Chief Engineer, Jordan Motor Car Co., Inc.

Design Improvements Suggested

Editor, AUTOMOTIVE INDUSTRIES:

The question—What is the next logical step in passenger car design and how can it be realized?—may be answered briefly by stating: The adoption of minor improvements which increase the facility with which the owner may maintain his car in good working condition and have it overhauled and repaired when necessary.

The car of to-day is a reliable piece of mechanism and capable of withstanding a surprisingly great amount of neglect and abuse. In the hands of the ordinary driver, the average car will run for at least six thousand miles without much attention, but at some time it is necessary to adjust the valve tappets, steering gear and perhaps the rear axle or perhaps the radiator or its connections need repairs, which are minor matters and do not prevent the car from running. But the motorist of to-day is not satisfied with a car which merely runs and provides transportation; he wants a car which operates smoothly and without squeaks and rattles, and to permit the owner to continue to enjoy and take the full amount of pleasure from the operation of his car is the immediate problem of the engineer. The average operator does not know what his car costs to operate, and doesn't much care, as long as his car gives him that intangible pride of ownership of a sweet-running piece of machinery, which he can keep in this condition for at least two or more years, without an undue outlay of time if he does the maintenance work himself, or without a great expense if he has the work done for him.

The writer has owned and operated a number of cars of various makes and has, in some manner, been associated with the operation and care of a great many more, as well as having designed a few cars which have been successful as regards being the source of profit to their builders, and in all of these cars there have been features which could have been improved if sufficient thought had been given to the details which promote the ease with which they could be properly cared for.

Starting at the front of the car, it is necessary in most cases to do considerable work with the sheet metal parts before the radiator can be removed, and to remove and replace the hose connections unnecessarily great care, patience and persistence must be exercised; otherwise damage to some part will result. Why not have the metal parts attached to the flexible hose connections made easily removable by taking off a few nuts or by unscrewing a simple metal coupling, and why put the bolts which hold the radiator in place in positions where they are so difficult of access? Further, in connection with the radiator, why not provide a deflecting apron behind the fan to direct the dust-laden air coming through the radiator away from the motor compartment toward the ground, instead of against the motor, where the dust will accumulate and where the carbureter will draw in large quantities of foreign matter, which causes unnecessary wear of the interior of the motor? Experience has shown that, with a properly designed cooling system, it is not necessary to have the fan blow the dust-laden air through the motor compartment.

Reverting to the sheet metal work at the front of the car, everyone knows that to remove a front fender or splasher requires more time than is necessary, because of the large number of small bolts or screws necessary to prevent excessive vibration, squeaks and rattles of these parts. Why not securely fasten these sheet metal parts to the frame, independent of each other in such a way that any of the parts can be removed without disassembling any other part? This merely means that each part will be designed or braced to be sufficiently rigid to withstand vibration, without depending on some other sheet metal part to provide the necessary rigidity.

Referring to the motor compartment—very few motors are free from serious oil leaks, even when new. The joints between the valve tappet covers and cylinder blocks leak oil, no matter how tightly the bolts or nuts on the covers are drawn. This defect is due to improper design of the covers, the fastening means, or the packing used, and instead of using one or two nuts in the center of the cover to hold it in place, cap screws along the edges of the plates should be used, because the extra work of removing a few additional easily accessible nuts or screws is not objected to if the motor can be kept exteriorly free from oil, which, with the dust drawn through the radiator, causes the average motor space to become a grimy mess, instead of the clean, neat compartment which it well might be, with pride to the owner and credit to the builder. Another serious source of oil leakage at the motor exists at either end of the crankshaft where it passes out of the casing. Most manufacturers are satisfied to provide an annular space surrounding the end of the shaft, feeling that they have made provision against the escape of oil at these points. Why not put oil-throwing rings on the shaft ends and provide a series of close-fitting annular grooves in the casing, with ample means for draining the oil back into the crankcase before it leaks out on to the road or the garage floor? I think that, judging from the oiled appearance of streets used by numbers of cars and from the appearance of garage floors, a surprisingly large amount of oil is wasted in a manner which is preventable, and by being wasted causes expense far in excess of the value of the oil.

It is possible to dwell at length on possible simple improvements in the design or location or mounting of the parts in the engine space, which will make it easier to properly clean and maintain these parts and be reflected in the increased life and better operation of these parts, but space does not permit of a detailed consideration of the subject at this time.

Briefly referring to other parts of the car, why not eliminate, as far as possible, all necessity for providing oil or grease lubrication of parts, particularly those inaccessibly located under the car? For instance, the use of small, laminated leaf springs, arranged vertically at the ends of the chassis springs, to take the place of spring shackles, which might also be replaced by using flexible fabric materials, such as cotton belting, working in tension to connect the ends of the springs to the chassis. Why not, also, use some form of universal joint, either of the fabric or spring type, to replace the grease throwing type now in common use? Why not have the floor of the body over the rear axle removable, so that lubrication and care of the center part of the axle can be accomplished without the necessity of getting under the car and ruining one's disposition and

clothing? Why not provide felt or other materials to pack openings in gear cases, etc., through which shafts pass, and by experiment determine the best packing material in each place, as well as the best way of providing a suitable means of keeping the joint tight during long periods of use? Using a piece of clock spring, surrounding the packing so as to press it against the revolving shaft, is a simple and cheap means of preventing oil seepage between the shaft and casing. Another source of messiness is where the gear shift rods pass through the ends of the transmission casing. Why not extend the casing, or provide a cover to enclose the ends of the rods, so that the lubricant which always leaks out at this point will drain back into the case?

A great deal of work has been done to improve the operation of the engine, and much has been written about increasing the fuel economy of the engine. This work is appreciated by all, but it seems inconsistent to devote so much attention to the engine and so little attention to the other power-consuming parts of the car. For instance, an investigation will disclose that the majority of cars having brakes which operate efficiently, also lose considerable power due to the dragging of the brakes. It is strange that this should be so, but the fact is that particularly with the foot brake, unless the adjustment of the brake shoes and their operating parts is such as to necessitate a movement of from four to five inches of the pedal pad, the brake will be found to drag. The average operator enjoys driving most when a movement of from two to three inches applies the foot brake, and this movement, with properly designed brakes, is sufficient and does not necessitate more than a nominal amount of force against the pedal pad.

The preceding few examples serve to indicate that a number of little things must be properly thought out and embraced in our car constructions before we can sit back and satisfactorily contemplate the results of our efforts, and I suggest that one of the surest and best ways of improving our cars is for the designer to operate one of his own cars over a protracted period and be compelled to care for it in all respects, including keeping it cleaned, without assistance. Such a policy will serve to familiarize the designer with the amount and nature of the disagreeable work necessary to keep his creation working efficiently and in such a condition that an owner may take pride in its possession and pleasure in its operation.

JOS. A. ANGLADA.

Improving Truck Design

Outside Factors Affect Truck Design

Editor, AUTOMOTIVE INDUSTRIES:

The probable future developments in truck design constitute a subject which it is difficult to treat in other than the most general terms.

The truck is a tool of commerce, its particular function being the transportation of goods. The outstanding feature of merit is its elasticity in use, due to the fact that it operates on the public highways. As a tool of business it must demonstrate its utility by an adequate return on the investment which it represents. Its earning power is affected by (a) its ability to work and (b) the cost of operation. The first item, the ability to work, is governed by design features and by the character of highways over which and the traffic conditions through which it operates. The cost of operation is partly dependent upon the design, workmanship and material employed, and partly upon facilities which are provided for maintenance.

With this brief outline of what I consider fundamentals, I would say that it is my belief that the increased economy of operation of trucks, by increasing the amount of useful work which can be obtained, depends primarily upon the future development of an adequate system of highways, the rearrangement of terminal facilities to eliminate loss of time loading and unloading, and the development and use of special types of bodies, mechanical and otherwise, for specialized application. As these things are accomplished I foresee the opportunity of developing trucks which will be more economical in operation, due to the fact that the size of motors and power plants and chassis can be reduced for a given useful load which will permit of more economical operation.

This same factor will make possible the use of pneumatic tires for larger specific useful loads than is possible at the present time, thus making possible the saving which can be realized in maintenance by the use of pneumatic tires, as well as economies which can be realized due to the larger amount of work which can be done with pneumatic tired vehicles, due to increased speed possibilities.

While mechanical development will undoubtedly proceed along various lines which it is impossible to specifically predict, resulting in simplification of parts with coincident reduction in labor and material cost for maintenance, I am inclined to feel that as a general thing a more thorough and systematic development of facilities for maintenance by large users for their own fleets and by manufacturers and distributors for the use of individual owners can be developed to realize the full benefits from present mechanical constructions. In other words, I feel that present designs are, on the whole, in advance of facilities which are in general existence even though they may be far from an ultimate state of perfection.

I realize that this letter is, as I indicated in starting, lacking in that it does not deal with specific items, but I have purposely refrained from doing this for the reason that there is undoubtedly more than one way along which developments will proceed, and if I should, therefore, deal with any one specific line, I would only be writing advertising copy as to the advantages of my own personal opinions on details.

B. B. BACHMAN,
Autocar Co.

Truck Engine Efficiency

Editor, AUTOMOTIVE INDUSTRIES:

It is rather difficult to pick out any one element in truck design and say arbitrarily that this is the element which is capable of greatest improvement. There are so many possibilities for better trucks along the lines of greater accessibility, easier riding, lighter weight, lower operating costs, etc., that one cannot pick out any one of these features and say that it will do most to bring about an improvement in trucks.

The weakest element in the design of the truck is undoubtedly the engine. Records show that from 80 to 90 per cent of the repairs and replacements on trucks

in service are required by the engine. This would indicate that there would be more possibilities along the line of improvement in engine design than in any other direction.

We must remember, however, that the present-day engine is a decidedly complex machine, combining as it does electricity, electro-magnetism, chemistry and thermo-dynamics, in addition to the highest order of mechanical ingenuity. When one thinks of it, it is really a wonder, as the farmer said, that the "durn thing runs at all." I, therefore, hesitate to criticize the present type of engine, although statistics indicate that the greatest possible improvements must be made in the power plant.

If someone can develop a power plant which will operate at reasonable efficiency under all conditions, and particularly under partial loads, and at the same time simplify the design so that the numerous delicate, highly refined parts and accessories can be eliminated, we will have taken a greater step forward in the design of trucks.

There is one point in truck design which, I believe, has been overlooked or on which, at least, we have not placed sufficient stress. I refer to the necessity of so designing trucks, and passenger cars, too, for that matter, that the shocks on vital parts may be reduced to the very minimum.

A truck is consigned to the junk heap ordinarily because of, first, obsolescence of design; second, excessive wear on vital parts, or, third, the breakdown of vital parts due to fatigue resulting from shock stresses. Certainly not over 10 per cent of the old trucks are scrapped because the design is obsolete.

Engineers are paying a great deal of attention to the use of adjustable bearings, renewable bushings, etc., so that it should be possible to renew a truck almost indefinitely, so far as wear is concerned.

In addition to all this, however, it is very essential that the design of the truck be such that it will accept or absorb shocks without injury to itself. The truck which is built on the rigid basis, with the idea of resisting such shocks, is at a serious disadvantage in this respect. A man jumping into a life-net escapes injury. Another, jumping the same distance onto the pavement, suffers serious injuries. In the former case the shock of landing is cushioned. In the latter it is rigidly resisted. The cushioning principle will help the life of the truck in similar manner.

CHARLES GUERNSEY,
Chief Engineer, Service Motor Truck Co.

Spring Shackle Action

Editor, AUTOMOTIVE INDUSTRIES:

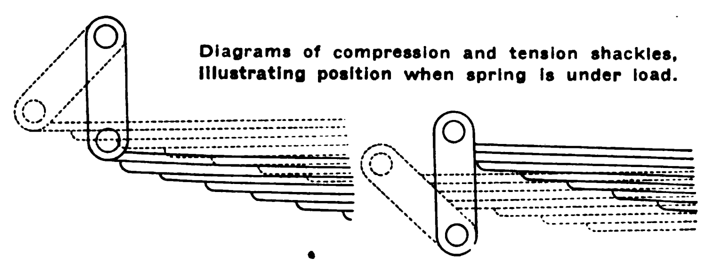
The query covered by your letter is:

"What do you consider the weakest element in truck design to-day and what suggestion have you for remedying it?"

It is exceedingly difficult to point out any one feature of design which represents the weakest point in motor truck design, inasmuch as there is room for so much discussion as to the relative importance of various portions of the chassis and, therefore, the importance of any weakness which might be general in such portions. Also, certain weaknesses which are flagrant in some chassis are not present in others, and so it is not fair to apply such cases to the whole art of motor truck design which can only be applied to a minority of vehicles. Therefore, in presenting one weakness in motor truck design, which I think it fair to say is common to all motor trucks in greater or less degree, one need not necessarily maintain that this weakness is the greatest in the whole structure.

One of the most important elements of motor truck structure requiring improvement at the present time is that of suspension. Good springs are available to those in a position to pay the necessarily high prices, and effective means have been developed for satisfactorily attaching such springs to the axle in a secure and rigid manner, but methods of securing the ends of springs to the chassis frame are generally crude and unsatisfactory.

The vehicle spring operates under distinct limitations. Although it is capable of cushioning the major shocks received from the road, other means are necessary to dampen the vibration not absorbed by the tires which, while of small amplitude, is of high frequency and almost continuous duration. Another limitation of the vehicle spring is that its cushioning qualities depend upon the pressure upon the spring. In light vehicles this pressure is fairly constant, the weight of the load, such as passengers in a touring car or packages in a light delivery car, does not materially change the pressure at the springs, but in motor trucks, particularly of the larger capacities, the load often represents more total weight than that of the entire chassis, and hence the percentage of capacity load carried materially affects pressures on springs. If a spring be designed for normal maximum carrying capacity of the vehicle, it will provide the



Diagrams of compression and tension shackles, illustrating position when spring is under load.

greatest cushioning effect under such conditions, and such conditions only. When running without load, the spring, on the contrary, will show little if any cushioning effect, so that not only are the minute vibrations transmitted direct from the wheels to the frame but the major shocks also.

Various efforts have been made to provide springs or spring systems having a greater range of cushioning ability. For example, some of the large bus operating companies employ springs having two separate groups of leaves, the upper group of small capacity, which provides good cushioning effect for light loads, and a lower group so cambered that it does not come into play until the upper group has deflected for a distance equivalent to a heavier load, whereupon the second set reinforces the first set to provide the requisite cushioning effect for a heavy load.

The dearth of rubber in Germany during the war gave rise to the use of helical supplementary springs instead of the customary shackles in order to absorb some of the vibration incident to the use of steel tires. The German "Gaggenau" have always used helical supplementary springs at the ends of their leaf springs. The use of shock absorbers, supplementary springs and snubbers of various types is very general on touring cars. The Hotchkiss drive has enjoyed considerable popularity in both touring cars and commercial vehicles on account of the superior performance attainable through flexible torque reaction resistance, and also because such suspension decreased the shocks and vibrations resulting from propulsive stresses.

Study of the action of the ordinary spring shackle

reveals the fact that the crank action of the shackle under some conditions has a peculiar binding effect upon the spring. Thus the compression shackle (see cut), when the spring is under load, permits the spring-eye to rise in relation to the frame. The greater the distance, the greater leverage the spring has upon the shackle, so that the return of the spring to its normal shape and the shackle to its normal shackle position is resisted; on the other hand, the tension shackle under the same conditions has this leverage reversed against itself so that the return of the spring to its normal shape is accelerated rather than retarded, since the distention of the spring has a tendency to raise the frame rather than lower it. A study of these actions will reveal that the effect in either case is undesirable, since in the case of the compression shackle the tendency is for the shackle to fall to one side or the other, thereby tending to restrict the return of the spring to its normal shape, while in the case of the tension shackle the effect is to keep the shackle in a position resisting spring action under impact.

The greatest drawback to the spring shackle is the necessity for two wearing parts whose friction is of the disadvantageous type; namely, oscillation rather than rotation. Unit pressures on spring and shackle bolts are excessive for the sizes in which they are ordinarily made, adjustment to compensate for wear is practically impossible and adequate lubrication is not only exceedingly difficult from the mechanical standpoint but most precarious from the human standpoint.

Another serious drawback to the conventional spring shackle is the lack of provision against side thrust; friction and pressure between the jaws of the shackle. Lateral stresses transmitted by the springs to the frame are of considerable moment and take place while the shackles are in motion. These result in wear and this wear leads to play with the attending results of rattling, endwise friction on spring and shackle bolts and admission of dirt and water.

Development of spring shackle design, therefore, calls for the provision of means to dampen the minute but destructive vibrations which the spring transmits to the frame, elimination of the undesirable crank motion of the spring shackle and a means of compensating for the necessary endwise motion of the spring tips without employing oscillating or sliding metallic surfaces requiring lubrication. Developments are now in progress whereby it seems that these ends can be attained by the employment of a yielding enclosure of the spring end composed of a plastic element capable of retaining the spring in general relation to the frame; capable of accommodating itself by deformation to the endwise movement of the spring tips without surface friction; adapted to constraining this endwise motion to a direction parallel with the frame, possessed of dampening properties whereby the vibration from the spring may be insulated from the frame end, not by accumulation into vibration moments of greater amplitude and slower speed, such as is the action of cushioning means, but by converting such vibration into kneading action upon the plastic body, as in solid rubber tires.

From present developments it appears that it is practicable to use rubber for this purpose, there being no necessity for an excessive volume of rubber, inasmuch as the rear spring has two such sections and need not have a greater volume of rubber in both upper cushions greater than the volume of rubber represented by that portion of the tire in contact with the ground; indeed, this volume may be even less, since the weight of the spring itself, the axle and wheel rests upon the tire but does not rest upon the ends of the spring.

This solution of the problem need not necessarily be the sole solution, but is here cited merely to show what possibilities along this line do exist and only await the concentrated attention of engineers to effect a much-needed improvement in this one detail of motor truck construction.

M. C. HORINE,
International Motor Co.

Horse Power and Horse Sense

Editor, AUTOMOTIVE INDUSTRIES:

In an endeavor to tabulate the troubles which were serious in the motor trucks used by the A. E. F. the writer surveyed numerous repair units, overhaul parks and the main reconstruction shops in France. In view of the fact that the A. E. F. at one time had in service approximately 169 different makes of motor vehicles (this figure includes trucks, passenger cars and motor cycles) it will be seen that the survey was fairly comprehensive and included prominent makes of trucks as manufactured in the various allied countries.

A careful analysis of this survey did not show that any particular element gave universal trouble in the various makes of trucks. It was generally found that each make of truck had its particular weakness and that the hard usage in army service brought out this weakness forcibly. The following is a brief list of troubles developed by different American trucks: exhaust valves, push rods, fan studs, motor lubrication, clutch, steering gear, steering arms, springs, axle housings, rear axle bearings, frames, etc. Taken by volume approximately 90 per cent of the troubles were found to be in the various units to the rear of the engine. Lack of attention to details of design and of assembly on the part of American builders was a constant source of trouble.

A comparison of the tractive factors developed in high gear by the average American truck with those developed abroad will show that the American truck has more ability on high gear than its European counterpart. This excessive engine power overstresses and quickly develops any latent weakness in the other elements of the truck and causes trouble. Hence it is the writer's opinion that the weakest element in truck design is paradoxically the engine, which is too strong.

The fault for this lack of balance of design does not lie entirely with the truck engineer, but more often than not is caused by the personal equation of the company for which the design is made.

A truck sales manager not long ago was insisting that cylinders 1/4 in. oversize be installed on a truck which already had good performing ability. He was asked whether he was selling transportation or horse power. The answer came immediately, "Horse power, it's easier."

The public and truck salesmen should be educated not to expect passenger car performance of a truck and the truck manufacturer and engineer should be taught to produce a more balanced design and economical means of freight transportation.

Much can be said against our practice of over-powering trucks, such as maintenance, road damage, etc., but two points stand out clearly. First, the average truck to-day has sufficient power to carry a 100 per cent overload in high gear on hard level pavements. This condition invites overloading on the part of the truck operator and he does overload continually, with the result that every part from the clutch to the tire is a potential source of trouble and the one that fails first is the weak element. Second, as a result of too large an engine a condition exists which is not quite so apparent, but is of the most importance to

the industry at large, i.e., the gasoline wasted by these engines. If smaller engines were used in connection with proper transmission and axle ratios a probable increase of 50 per cent in ton miles per gallon of gasoline could be obtained, which would result in a national saving of fuel. Some of the fuel associations have been advocating this procedure, but so far without apparent results.

The weakest element of truck design might be paraphrased as *too much horse power and not enough horse sense.*

W. T. NORTON, JR.

Fuel Economy and Manifold Development

Heat Regulation in Manifold

Editor, AUTOMOTIVE INDUSTRIES:

More than ever before, the subject of economy, or more technically, efficiency of operation is occupying the attention of all involved in things which have to do with progress.

With the automobile this is caused by more than the mere outlet for the energies of the engineer—it has become imperative not only on account of the apparently diminishing supply of fuel but because of the general tendencies of everyone to retrench.

The problem is difficult not simply because of widely varying characteristics of the fuels available but because of the different conditions under which the engine is required to perform, and in which is included that of climate.

Theoretically a charge should be gotten into the cylinder at the lowest possible temperature if maximum power per unit of weight is desired, but with present day fuels this must be modified by the methods necessary in producing a mixture which is absolutely homogeneous.

Analysis of this will show that whatever modification or compromise in initial charge temperature is effected will be controlled by not only initial temperature of the air and fuel, but the load assumed by the engine as well.

With the two accepted mediums for affecting the temperature of the intake charge each has its advantages and disadvantages.

With water, there is always valuable time lost in arriving at a temperature sufficient to produce proper results, and when this has been arrived at, variation in engine power, unless for fixed amounts and sustained periods, finds itself contending with insufficient heat for large amounts of mixture passing by the throttle or too much for small amounts or possibly vice versa.

In addition, the maximum temperature available is seldom in excess of 180 deg. Fahr., and with the usual commercial forms of transferring heat this is quite insufficient.

Briefly summed up, use of the jacket water not only provides insufficient heat, but the range of variation is too small and the total amount of heat units held in reserve by the jacket water is so great as to make whatever change takes place too sluggish in its action.

It might be possible for some complicated arrangement to control, by means of thermostats and circulating devices, the rate of heat interchange, but a little thought will indicate that the complications involved would more than offset any thermal advantages.

The other commonly resorted to form—exhaust heating—possesses also a disadvantage as to amount of heat available for transfer, but from the other direction, it might be said. Under certain conditions it is far too intense, and in which case it results in cracking of the fuel or raising of the temperature of the intake charge to a point sufficient to offset by a loss in power any gain in thermal efficiency.

The ordinary forms of heating at present in use are not the most desirable because of the fact that there is no fixed relation between amount of fuel, quality of fuel, initial heat in the fuel, and the intake air and the amount of heat to be supplied, and which it will be readily agreed is just as essential of accurate gaging as is the timing of the valves, or ignition, or proportioning of the mixture.

The ultimate aim, then, is some form of heating element for the air or fuel or both, and which shall deliver to these portions an amount of heat sufficient to produce a definite temperature of the whole mixture, and which temperature shall have a definite relation to the amount of charge involved, basing this statement on the assumption that there already exists a definite control of the water jacket temperature.

To accomplish this there must first be an abundant supply of heat of minimum cost and which requirements are covered by the exhaust gases; secondly, a medium easily susceptible to temperature changes in order that the variations may be as rapid as required; and third, a thermostatic device which will establish a definite relation between these variables, and which relation can only be determined for a given type of engine and carbureter by careful dynamometer and road tests.

D. L. GALLUP, Consulting Engineer,
Nordyke & Marmon Co.

Induction Gases

Editor, AUTOMOTIVE INDUSTRIES:

Considerable discussion has been accorded the various methods of conditioning gases entering the combustion chamber of our various motors of to-day; and now that everyone is—or claims to be—fairly well "hot-spotted," it is time to call attention to another factor—that twin companion of misery—proper distribution of induction gases.

Reverting to the history of hot-spot records in the S. A. E. Journals of 1916 and 1917, it will be found that discussion first started regarding the application of heat to induction pipes. It has taken four years to recognize and admit the fact that heat properly applied to induction pipes is beneficial. Let us hope that it does not take a corresponding period to wake up to the fact that even after gases are conditioned the problem of proper distribution is still paramount.

Observation of the various forms of heat applied on induction pipes leads the writer to feel that the proper study and analysis of this problem has not been carried out by various designers, as some applications are clearly nothing more or less than hot induction pipes, which are not within the meaning of the term at all. Hot induction pipes make for soft motors, lack of economy, lack of power and frequent actual operating difficulties. Mr. A. L. Nelson's paper at the mid-winter S. A. E. meeting clearly brought out the factor involved in proper hot-spotting, namely: excessively hot localized stricture of induction gases in such a manner that the heavier or wet content can not pass a given area unless it passes through the medium of the air stream.

The only suggestion I can make in regard to Mr. Nelson's application is that to my way of reasoning, his exhaust is too far from his heated zone and he is not obtaining the hottest exhaust gases possible by this application.

Mr. Nelson states that the use of this device has enabled him to increase his induction pipe area as well as his carburetor sizes. This is very true and is as it should be.

This question of hot-spotting has been brought up at various semi-annual meetings of the S. A. E. and has been discussed and criticized most thoroughly by various members. Those of us who have been consistent users of the hot-spot have fallen back on the fact that, the slight loss in volumetric efficiency due to the induced heat through the hot-spot, is more than compensated for by the increased power obtained through the use of the induced heat from the hot-spot; and that, for the time being, we must rest on the fact until something better has been determined that will be as simple in its application as the hot-spot. Engineers, in general, had best confine their activities along this line and leave the more complex solution of the problem in the hands of specialists who undoubtedly will later on find a way through this maze of difficult carburetion.

The "twin companion" indicated at the opening of this article, that has not received the attention it deserves, has been the distribution of gases. On four-cylinder construction this distribution has been reasonably simple. However, on six-cylinder construction and other multiples thereof, we find this problem of distribution becomes exceedingly complex.

The proper application of the hot-spot at the carbureter branch will get the gas beyond this branch in fairly usable condition. However, the breaking up of the liquid fuel into minute globular particles, which pass into the combustion chamber in the form of fog, does not indicate that the density of this fog-like fuel is uniform in the least. The mass difference of this charge can be well demonstrated experimentally by laboratory means.

In passing such a charge through pipes of various bends, it will be noted that the heavier globular particles suspended in the fog have a tendency to hug either one side or the other of the pipe, at the point of its ejection. Consequently, there is no basis for the assertion that a right-angle pipe will eject a uniform mixture of the fog-like fuel at absolutely right angles to its point of entry into the pipe. Therefore, the application of pipe bends is of great importance, even when combined with the hot-spot system of rupture of fuels. Care must be exercised to so design the entry of the gases into the cylinder block that these heavier elements of our fuel are not thrown toward the end cylinders or toward the center cylinders, as the case may be.

This is particularly true on six-cylinder construction, where a block of three cylinders is served by one branch of the induction pipes. It is usually the practice to favor the two end cylinders with the bulk of the charge, in the hopes that by their increased capacity they will absorb the bulk of the heavy elements without disturbing the general functioning of the motor. These conditions generally result in the starving of cylinders Nos. 3 and 4 to some extent and build up different pressure readings on explosion cycles.

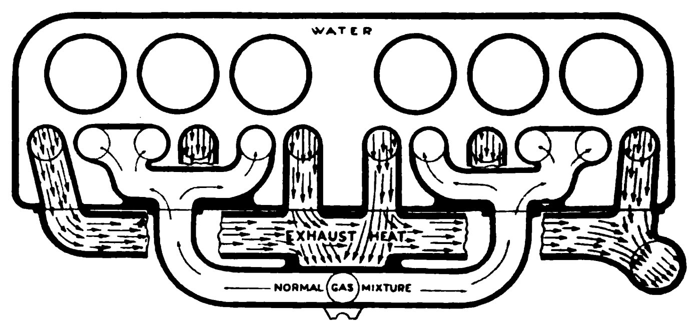
The purpose of the above discussion has been to bring to the attention of engineers the benefit accruing from the so-called ram's horn construction of manifold. Through the use of such manifolds with the ram's horn effect—either up or down—we have been able to introduce the fog-like gas in such a manner as to equally distribute between any one of a group of three on six-cylinder application. In the formation of the intake passage of a group of three on six-cylinder application, it is necessary that the cored passage in the cylinder block be a continuation of the idea involved in the ram's horn manifold.

The advertising manager who seized upon the hot-spot and ram's horn slogan built much better than he knew at the time. Great attention has been given to the hot-spot feature; but the question of proper distribution of gases after passing the hot-spot has, I feel, been sorely neglected.

Another important factor has been overlooked in this battle for efficiency. We are running our engines too cold. When one considers the possibility of air cooling, one must consider that the normal operating temperatures of such motors exceed the operating temperatures of the average water-cooled engine by at least one hundred per cent.

If these things are possible with air cooling, it is also possible that a vast improvement can be made in water cooled construction. Our compressions, fuel density, etc., have been calculated subconsciously with the idea of using water as the cooling medium. This has restricted our pressure requirements on both compression and explosion to that point where the boiling point of water has determined practically the maximum obtainable without the actual breaking-down of our fuel structure.

Even though the above statement has been worked out in theory, facts indicate this is not the ease when looking over the field in a broad manner. We are not even utilizing the benefits to be obtained by taking advantage of the average boiling point of water as a maximum possibility. Most motors under normal operating conditions do not exceed 120° to 140° of heat, whereas the greatest benefit for their particular compression ratios would probably indicate 190° to 200° of heat would be more desirable.



It seems, then, that we have neglected entirely this question of maintaining the highest normal operating temperature to which our engines are designed. Great advantage can be secured by increasing this temperature to the maximum, and through such method of control, by guaranteeing that evaporation will not become a disturbing factor; or some means be instituted to prevent evaporation through the condensation of the cooling medium.

After the hot-spot has done its work of rupturing the tough liquid fuel with which we have to deal to-day, and properly designed manifold has introduced this fuel into the combustion chamber in such a manner that each cylinder draws an equal part of this mixture, it is necessary that this fuel be handled in such a manner in the combustion chamber that the maximum expansion possibilities are obtained from it.

This can only be so by maintaining piston wall and head temperatures of sufficiently high degree that our fuel will not recondense on the surfaces of these parts; but will rebound, so to speak, from these parts on compression—thereby agitating the mass and increasing the speed of the combustion.

Taking the writer's argument as a whole, it is incumbent on the profession to not become so fully absorbed in this question of hot-spotting or conditioning of gases as to neglect the proper distribution of such gases after being conditioned and the treatment of such gases after being distributed.

C. C. HINKLEY,
Hinkley Motors Corporation.

Necessity for Fuel Economy

Editor, AUTOMOTIVE INDUSTRIES:

It is doubtful that there is any one problem that is given more thought by the engineers of the industry to-day than that of economy and every one of its many phases, the principal one of these phases being that of the economy of fuel. The motoring public of to-day has had borne upon them in the last six to ten months the tremendous necessity of economy throughout the entire nation, and immediately brings to the surface the things that have been uppermost in the minds of many engineers for some time to come.

I believe the greatest problem that the automotive engineers have to face to-day is that of producing an automobile or any automotive apparatus that will function with the maximum economy of fuel, lubrication, service upkeep and represent a high second hand value. I am thoroughly convinced that this demand for economy is bringing forward the best efforts of all engineers and we will undoubtedly see in the not too distant future many changes in the designs of many of our most popular automotive vehicle development along the lines of particular fuel economy. Much of the engineering work that was done during the war, particularly on high duty engines for airplanes, tractors and much of the war apparatus, presented an opportunity to the engineers to make some vast strides in cylinder efficiency. This development work is being commercialized by the engineers throughout the industry and its effect is already being felt.

In reference to the question as noted in your letter as to the advantages and disadvantages of a cast iron camshaft bearing, where the bearing is simply a drilled hole in the crankcase compared with a bushed bearing. It is my belief that the bushed bearing is the most satisfactory type as it presents many advantages in manufacture, as well as tremendous advantage in service in the car owner's hands. This is something that will have to be considered more than it ever has been before. We are, however, advocates of the cast iron camshaft bushing. We have used successfully on something over 200,000 engines a cast iron camshaft bushing inserted in the crankcase. While it is necessary to be a little more careful regarding the hardness at the bearings so as to make this bearing smooth, it is without a doubt the most satisfactory camshaft bearing that could be put into an internal combustion engine of multicylinder type.

A. C. HAMILTON, Chief Engineer,
Oakland Motor Car Co.

Economy of Operation Coming

Editor, AUTOMOTIVE INDUSTRIES:

It appears to me that economy of operation will be the next step in passenger car design, and that the gasoline consumption problem is the biggest item under this heading. Eventually economy of fuel may be accomplished by the use of some radically different types of motors or other more or less revolutionary changes, but there will no doubt be an intermediate step which could be made almost immediately.

In view of modern engineering developments, this step, I believe, will be the installation of smaller motors and some transmission device permitting the motor to operate most of the time at or near its maximum efficiency. There may be developed at some time in the future to a practical point what we might call an ideal transmission with an infinite number of speed ratios and a comparatively simple control, but for the present for practical purposes we are almost limited to a four-speed transmission of the ordinary design.

By using a motor of such size that the maximum speed of the car would not be over 45 miles per hour, and by the use of a four-speed transmission it should be possible to increase the mileage per gallon of gasoline by at least 50 per cent very easily. This fact, of course, is well known by automotive engineers, but probably not very generally known by the public, and I feel that when the public really become acquainted with such conditions and when they are ready to make a few practical sacrifices for the sake of economy that this step will no doubt be taken.

It should not be a great hardship for the average driver to have the maximum speed of his car limited to 45 miles per hour, as this is even beyond the legal limit in most communities and much greater speed than can be used with comfort on the greater part of our roads.

There should also be very little objection to more frequent shifting of gears, particularly if the operation were made more simple and convenient by the use of some of the so-called automatic arrangements that are now being developed to a very practical point.

As a general proposition, the buying public gets what it wants, and my opinion is that when it really wants economy and is willing to make some very minor concessions to obtain it, the automobile manufacturers will very gladly and can very easily give it to them.

C. S. POPE,
Chief Engineer, Elgin Motor Car Corp.

Some Interesting Comment on Four Wheel Braking

Disadvantages of Four Wheel Braking

Editor, AUTOMOTIVE INDUSTRIES:

Answering your query in regard to the use of four wheel brakes on high class American cars, I believe the following considerations should be looked into.

There is a possible limit to the retardation of a motor car with respect to the comfort and safety of the passengers. It is no uncommon thing with the quick application of the brakes on two wheels only to have passengers thrown from their seats. It is for this reason that in high class passenger cars easy acting brakes are a requisite, but even with soft or easy acting brakes it is possible in an emergency to retard the car so rapidly and so suddenly that passengers not on their guard may be given a most uncomfortable feeling, if not actually thrown from their seats.

Therefore, it is a question whether the proper amount of braking is not already provided on the standard jobs of to-day, providing the brakes are properly designed and applied. Placing four wheel brakes on a standard high class job would increase the discomfort in driving when brakes were used quickly to the limit and many accidents to passengers, especially children, would result.

The advantages claimed can only become advantages where cars are operated at excessive speeds or at speeds incompatible with the state of the weather or pavement. For sporting cars, racing or record breaking cars, the advantage of the four wheel brake is without question, but in order to demonstrate the advantages a driver immediately has to drive recklessly and at speeds contrary to police regulations and most of the State speed laws.

In most cases four wheel brakes would be much more

difficult to keep in order and adjustment than the present two wheel brakes.

All in all, it seems that the present braking system when properly designed and installed is satisfactory. Why add to complications for the unnecessary?

W. R. STRICKLAND, Chief Engineer,
Peerless Motor Car Co.

Advantages of Four Wheel Braking

Editor, AUTOMOTIVE INDUSTRIES:

Replying to yours of recent date, note your question in regard to whether four wheel brakes would be an advantage for high grade American cars.

From the experiments made, I am rather inclined to believe that they would be an advantage on any car weighing over 2000 lb., provided the front wheel brakes are made in some simple way so as to eliminate the complicated universal joints which are sometimes used.

From the experiments made, I find that it is possible to stop a car equipped with the four wheel brakes in between 50 and 60 per cent of the distance required for only the regular two rear wheel brakes. Also skidding is very materially minimized by the use of the front wheel brakes, provided brakes are properly equalized. If brakes are connected up properly they are a great help in descending a steep hill, as it allows one to cool off one set while using the other.

There is, no doubt, some disadvantage in the use of front wheel brakes, due to the additional cost and to the slight complication necessary and also to the additional weight, but I believe that the disadvantages are more than offset by the advantages. W. G. WALL,
National Motor Car & Vehicle Corp.

Three Is a Crowd in Rear Seat

Editor, AUTOMOTIVE INDUSTRIES:

We have had a car fitted with four wheel brakes in use for the past six months—while this car enables wonderful demonstrations to be given, yet its ability to stop in a shorter distance than our car, equipped with rear wheel brakes only, is obtained at considerable discomfort to the passengers. With only rear wheel brakes properly adjusted and the brakes adequate in size to the car weight, a car can be stopped as rapidly as is desirable.

It is wonderful how quickly a car equipped with four wheel brakes can be stopped—a car fitted in this manner can be stopped in less than half the distance of a car equipped with rear wheel brakes only. Theoretically, this should be impossible, but probably because of the load being thrown on the front wheels there is greater traction on the front wheels than exists in theory, and a car can actually be stopped in less than half the distance with four wheel brakes than it can with rear wheel brakes only, even though rear wheel brakes are powerful enough to lock the wheels. When a car equipped with four wheel brakes is stopped in the shortest possible distance it is extremely uncomfortable for the passengers, and, unless they have something to hold on to, they will be thrown out of the seats very violently. Of course, having four wheel brakes does not necessitate violent application of the brakes, and the advantage then is that a car can be brought to a stop in the usual distance with much less effort on the part of the driver; this is not of very much consequence, as most cars are equipped with brakes that are large enough that they will almost lock the wheels without any excessive effort on the part of the driver. It is always desirable to stop short of locking the wheels.

Another advantage that probably is possessed by four wheel brakes is the life of the brake lining and the length of time that one can run without necessitating readjusting the brakes. If a car is stopped in the usual distance and having double the number of brake drums will, no doubt, double the life of the brakes. This is, of course, desirable, but as to whether this is necessary will depend upon the amount of trouble this gives on a given car.

One other claim is made for four wheel brakes, and that is that a car is not so likely to skid when the brakes are applied on wet pavements. In some cases this is certainly true, in others the driver sometimes loses his control over the front wheels with four wheel brakes, and we have seen cases where cars have swerved very objectionably to the side of the road.

Most four wheel brakes that have come to the writer's attention have been very complicated; in many cases the front springs and front steering pivot axles are unduly stressed. It would appear that these parts should be made much heavier than usual when front wheel brakes are applied.

Body Design

There is another matter in which I believe you could be of much use to the automobile industry by having a discussion in your journal, and that is by advocating that no passenger car should be designed to carry more than two full-grown people on the rear seat. There has been a great demand by the automobile buying public for years for a very wide rear seat that will be quite comfortable for three grown-up people with overcoats and robes. This could be accomplished in the old days, when the chassis was very high from the ground and the body and seats also very high; then the passengers could be accommodated in regard to width by a cushion being carried out sideways over the rear wheel housing, but in the present-day cars, where the chassis and bodies are low, the rear seat must come in between the rear wheel housing, and it is utterly impossible to give comfort for three people if the standard tread of 56½ in. is adhered to.

We firmly believe that the tread should neither be under nor over the standard because of having to so frequently run in ruts; this, therefore, being limited, and the cross section of modern tires being much larger than in the past, makes it quite impossible to obtain a width of rear seat that is adequate for three full-grown people. Provision must always be made for the use of tire chains, and ample clearance must be allowed between the sides of the wheel housing and the wheel to accommodate side sway of the body, and this, when properly taken care of, gives a rear seat adequate for about two and a half people. It makes a much better proportioned car when the width is kept down to accommodate two people in the rear seat, and the spring suspension is a much easier problem.

It is a very rare thing to see a seven-passenger car on the road with seven people in it, and if the springs are adequate to take care of three full-grown people on the rear seat, they will give hard riding when only one or two passengers ride on the rear seat.

It will be quite a boon to the body designer, chassis engineer and the makers of springs if cars of two, four or six passengers were the limit, no seat being made wider than to take care of two grown-up people. If the above facts were brought forcibly before the buying public there might be less demand for wider rear seats than can at present be provided for.

D. FERGUSSON,
Chief Engineer, Pierce-Arrow Motor Car Co.

Weak Elements of Present Tractor Design

Lugs on Wheel Type Tractors

Editor, AUTOMOTIVE INDUSTRIES:

"What do you consider the weakest element in wheel type tractor design to-day, and what suggestions have you for remedying it?"

Hubs, spokes, bearings and, to a certain extent, the rims have received considerable attention in tractors, but it can hardly be said that lugs have had the serious attention they must have before we can call them an engineering solution.

Practically all lugs have been made up to use cheap commercial structural shapes; the methods of attaching and detaching are in need of more study to produce quiet and simple operation and removal. Interchangeable wheels with sets of various type lugs is one solution. On the whole, however, the real question is "A series of correct lugs to meet variable conditions of road and field, designed in such a manner as to use to the fullest extent a minimum tractor weight along with the minimum of energy and disturbance of soil, secure the maximum sensible area of soil contact and still keep within the shear value of the soil."

A reasonable possible slippage should be incorporated in the design at or near the point of maximum drawbar pull on low gear, for the reason that we need a safety slip for the energy when plows strike obstructions which might be considered irresistible.

It would seem that a real research series is necessary to cover the various problems of lug and wheel action. We should know some of the following relations:

1. Bearing areas and pressure distribution of round wheel and caterpillar type treads, standing still and in translation.
2. The proper theoretical form of lug for various general groups of soils to give us the best possible hold on the ground in translation, covering also various soil moisture contents within the range of practical plowing.
3. The relation between weight of tractor and lug penetration of various forms.
4. Friction relation of flat steel tires, weight on axle, wheel diameter of face on various soils, covering various moisture content within practical tractor operating conditions.
5. Soil friction or shear values between flat areas of typical soils.

When we have these relations, and doubtless some others, we shall have gone a long way toward reducing rolling friction and making a tractor more generally efficient.

Another series of problems relates to gear tooth design and efficiencies. We should answer this question: "What form of gear tooth will give us the longest life with a minimum of variation in the transmission of uniform angular velocity?"

We are all aware that new gears, well run in and under sensible load, have very high efficiencies, but this is only during the period that the tooth form and alignment is theoretically correct to transmit uniform angular velocity. As soon as wear takes place in the tooth or bearings, the form changes rapidly above and below the pitch line because of the combination of sliding and rolling contact, so that it seems very desirable to investigate these features of design more thoroughly.

There is little use of our reducing by extreme energy and careful and expensive design the fuel consumption by the 1/100 part of a pound of a given engine, and then throw it away in quantities of horsepower in the transmission wear and tear and translation losses. In other words, let us reduce the tremendous losses between the engine shaft and the drawbar by a detailed study of each intermediate group of frictional losses.

O. B. ZIMMERMAN,
International Harvester Co.

Tractor Adaptability to Field Conditions

Editor, AUTOMOTIVE INDUSTRIES:

If clarifying views on the one weakest element in wheel type tractor design to-day were wanted, I should choose to express myself on lack of adaptability to general field conditions. Much has been written and said about the lack of standardization or uniformity in tractor design and is almost always compared to the nice uniformity and standardization obtaining in trucks and automobiles at this time. According to the automotive engineer whose field has been limited to road vehicles, his prosaic contemporary in the tractor industry has been playing too much with the sand man. Altogether too frequently the vehicle engineer bursts forth in print and in production with a solution (?) of the whole tractor problem.

Let me point out here that the problems to be met by the tractor designer are fundamentally different and more complex than those to be met by the vehicle designer. The tractor designer has a multitude of conditions to meet, each one of which may call for a different basic design for his tractor if he is to meet them each with a separate type of machine, and here is where the vehicle engineer falls down in principle and creates one more type to be added to the already large number of existing types of tractors.

To me the greatest weakness in the present tractor design and the greatest problem to be met lies in the necessity for a machine which will meet the greatest number of conditions. Here the field for mechanical ingenuity is practically unlimited. No single-idea designer will succeed here. A designer must be conscious of all the conditions to be met, and in order to succeed must exercise rare and impartial judgment. The development of any industry is always based more or less upon precedent followed by evolution.

In the early days of tractor development precedent of the heavy steam tractor was followed and unfortunately for the industry is still followed by some large companies.

During the last few years, however, since it has been learned that suitable weight distribution, wheel area and lug equipment will give a tractor a drawbar pull equal to its own weight, there has been a substantial tendency toward something like a uniform type of tractor. Tractor design, however, will never reach such uniformity as is possible in vehicles.

The tractor of to-day has been accepted as a success in the fairer fields, but we still have millions of acres upon which the average type of tractor cannot be called a "howling success." The broad plains of our country have naturally been the ones where tractors were first successful, but as developments go on we always come up against conditions not exactly suited to the prairie type, and due to meeting conditions in the rice fields, sand dunes, swamp lands, hillsides and woods we are continually working toward the more adaptable machine.

The solution of the problem of making a tractor more adaptable to the varying conditions lies in, first, light weight, for light weight is desirable in all the conditions;

second, weight distribution in order to make available at the drive wheels all the power of the engine, and, third, general maneuvering ability which will make possible the successful operation of the tractor on hillsides, in orchards, in sandy land, in peat bog and in the harder gumbo and clay fields. Yours very truly,

R. O. HENDRICKSON,
Vice-President, J. I. Case Plow Works Co.

Traction Rating Variation Causes Injustice

Editor, AUTOMOTIVE INDUSTRIES:

The lack of proper lug equipment for tractor wheels is a decided weakness. For proper lug equipment I would consider a lug that worked fairly satisfactorily under a great variety of conditions which would avoid the necessity of changing the lugs with a change of soil conditions.

Another matter which seems to require attention is that of weight distribution, especially as it affects the slippage and guiding of the tractor. In our tests last season it was noticed that the slippage in tractors of different types, with exactly the same weight distribution and under practically the same conditions, varied materially. This would indicate that possibly there are other elements than the distribution of weight that affects the slippage. The guiding of the tractor is governed almost entirely by proper weight distribution, and in order to carry out effective guiding it is important that this matter should be given proper attention.

If I may add a word of what is considered the weakest element of tractor design to-day, I would say it is the wide variation of tractor rating. In our tests last year of 65 tractors we found that the ratings varied from 20 per cent below to 50 per cent above the actual maximum horsepower on the belt. This is too great a variation and works an injustice to all manufacturers.

OSCAR W. SJOGREN,
Chairman of Department of Agricultural Engineering, University of Nebraska.

Increasing Battery Life and Satisfaction

Factors of Original Battery Installation

Editor, AUTOMOTIVE INDUSTRIES:

In the earlier days of the automobile, there were two elements of the car which competed for the dubious honor of being the shortest lived, viz., the tires and storage battery. Both the tire manufacturers and the storage battery concerns have made wonderful improvements in their construction, so that now it is possible to obtain at least two or three seasons' use out of both tires and storage batteries.

Unfortunately, the battery problem is much more complicated than the tire problem, because the average driver carries spare tire equipment, and, even if he should not, it is possible, at the expense of small annoyance, to remove a flat tire and drive on the rim to the nearest small town or country garage, where he will usually find ample equipment to get him out of his trouble with very little delay. Should his battery fail, however, at a critical time, it may be impossible even to get the car started, and, on account of the almost universally adopted practice of storing the battery away in an invisible and sometimes inaccessible location, the owner is tempted to forget completely the very existence of his battery until such time as it ceases to function.

As previously stated, it is possible, by taking advantage of the latest improvements in battery design, to obtain several years' satisfactory service, but, on account of the very fact that a storage battery is tucked away out of sight, it has been the subject of what someone has called "Purchasing Department Engineering." Batteries have frequently been selected more on the basis of their first cost than that of the "most miles per dollar," which one of the tire companies has adopted as a slogan.

To show what this means to the owner, it might be well to take a typical example of two batteries submitted for a given installation. One might have a normal life of, say nine months, and cost the car manufacturer a certain basic price which we will arbitrarily say is $20. Another battery can be purchased for, say, $30, which would have a life of at least three years.

Now, let us see what happens in the first case. The owner purchasing the car with the lower-priced battery gets satisfactory service for the nine months, at the end of which time he must buy a new battery, for which he pays, not the same price as the car manufacturer, but a retail price which would be (in proportion, probably) $40. If he gets nine months' service out of this battery and repeats the operation, at the end of the three years he would have expended $120 for storage batteries, and be in exactly the same place as the owner of the other battery, who has so far not had to make any expenditure at all. Of course, you might say that at the end of his first period he might have bought a higher priced battery, and, from then on, had long life and satisfactory battery service; but the tendency is, as a rule, to install a battery of characteristics equivalent to the one originally used.

It is readily apparent from the above that the car manufacturer in saving $10 on the first cost of the car has placed the user under an expenditure of many times this sum.

In all justice, it must be admitted that the storage battery manufacturers themselves are to a certain extent responsible for this condition, because they have permitted, and in some cases advocated, the use of batteries with very thin plates and separators which showed very superior performance and characteristics on bench tests, but which, in order to meet these very tests, had to have the element of durability sacrificed.

Three requirements which most purchasing agents and some engineers have set up as a mark to shoot at are the three words, "small," "light" and "cheap," and the element of service has not been given its proper consideration. There are notable and gratifying exceptions to the practice, however, as I have in mind a certain car which carried complete electrical equipment in the year 1912, and on which (at the latest calculations) at least 30 per cent of the original batteries are still in service.

The location of the battery is of great importance; probably the best place ever found is on the running board, or in the space between the running board and frames so that it is in plain sight and easily accessible. But, on account of the universally desired clean running boards, the battery has been shifted to various locations in the body or chassis—some of them fairly satisfactory, but more often extremely unfavorable.

I have seen a battery located right alongside a hot exhaust pipe, under the floor boards, where it was necessary to use a screwdriver to take screws out of floor boards to get at the battery. The location alone was responsible

for considerable evaporation due to heat, and the irksome job of getting at the battery made the addition of distilled water, when required, a very rare occurrence, with the result that this installation gave very unsatisfactory service to say the least.

Another case of a two-door sedan—the battery was located on the chassis under the front floor boards, and only a human snake could get at it. The result, of course, was that it got attention only when something failed to work. The production engineer at the motor car plant wanted a battery installation, which was the same for all types of bodies, and gave but casual thought to battery accessibility.

However, as this whole proposition gets to be better understood, and the vital importance of a satisfactory storage battery to the service which the car can give becomes better understood, I believe there will be such co-operation between the manufacturers of storage batteries, electrical equipment and motor cars in the way of original specifications, battery location, both as regards accessibility and freedom from engine and exhaust line heat, road dirt, etc., that we can expect wonderful improvement in the general all-around service of this much abused piece of apparatus.

W. A. CHRYST,
Chief Engineer,
Dayton Engineering Laboratories Co.

Battery Satisfaction

Editor, AUTOMOTIVE INDUSTRIES:

We suggest the following in answer to the question, "What should car manufacturers do to render storage battery installations more satisfactory and to increase battery life?"

1. Location of the battery where it is easily accessible.
2. Battery should be placed in a container which will keep out all dust and moisture.
3. Battery compartment to be large enough to block the battery in with corner blocks and also have hold-down rods which can be easily removed when it is necessary to take the battery out of the compartment.
4. Battery leads should have enough slack in the cables to prevent any pull on the battery post which would cause the post to break.
5. All battery terminals should be thoroughly tightened with bolts and nuts and then covered with vaseline or some suitable grease to prevent the acid spray from causing corrosion.
6. Sufficient clearance should be allowed in all battery compartments to permit any standard make of battery to be used as a replacement on an automobile. This is especially true where a battery with an increase in height may be purchased by a car owner if he desires to use a battery of increased capacity over the one furnished him by the car manufacturer.
7. In the location of the battery, allowance should be made for the battery to use a type which is mechanically the best that can be built. The end to end assembly of the battery makes a very long case and very often necessitates the use of bolts to hold the sides of the battery box together.
8. Car manufacturer should see that a battery that is placed on a car has not been allowed to stand around in stock for any length of time. The car owner should be permitted to receive as new a battery as possible.

A very desirable method of doing this is to purchase a bone dry battery from the battery manufacturer and keep this in stock up until the time it is necessary to place it on the car, or better, ship the same bone dry battery with the car to the car owner.

9. The car owner should be given all the information in regard to the care of the battery and instructed to register his battery immediately at a battery service station.

It would be very desirable if the car manufacturer would keep a record of some kind which would give the serial number of the battery which is shipped on a car with his own car serial number. This would lead to better cooperation between the battery manufacturer and the car manufacturer and would result in more satisfaction to the car owner.

WILLARD STORAGE BATTERY CO.

Engineering Problems of Present Importance

Increased Compression Ratios

Editor, AUTOMOTIVE INDUSTRIES:

In reply to your letter of April 28, I consider you made a good guess in suggesting that I write about "increased compression ratios." My views on this subject sum up as follows:

(a) The degree of compression used in present day automotive engines is the principal deciding factor in the power output and fuel consumption of an engine of given speed;

(b) At the present time, the nature of our fuel is the largest deciding factor on the degree of compression which can be used;

(c) Given a fuel which will make possible the use of compression ratios of 6 or 7 to 1, we are certain of great gain in power and economy in all types of automotive engines;

(d) I believe the use of such high compressions with fuel giving no detonation or preignition, will not be materially harder on existing engines than the use of present compression ratios with present fuel, in spite of the fact that a much higher b. m. e. p. will be maintained;

(e) There is now much waste of fuel due to running automotive engines with "rich" mixture mainly for the purpose of reducing detonation, although few people have thought of it in that way;

(f) We must make non-detonating fuel universally available as soon as possible, for then only can we use high compression pistons in our engines and feel that we are running somewhere near as economically as we know how to, and begin to think of our old enemy carbon and his exciting influence on detonation, as a friend and an insulator conserving our dearly bought fuel;

(g) By the proper use of available benzol supplies, a large percentage of our present automotive engines could be run on fuel better suited to their present compression ratios but, unfortunately, where benzol is used, it is frequently used in proportions of from 50 to 100 per cent, whereas from 20 to 30 per cent is all that is really needed with present compressions; to permit the use of much higher compressions, the General Motors Corporation has made wonderful strides in finding compounds which, when added to fuel in exceedingly small percentages, make them satisfactory for use in engines of even 71 compression ratio.

In addition to the foregoing, I believe the most important automotive problems are: all-metal, internally braced aircraft; carbureters giving "leaner" mixtures through the throttle range, and air-cooled engines.

In the all-metal airplane, I see a type which will require less maintenance and will last longer, therefore, presumably, making it cheaper, and I know of much good work progressing along this line.

Referring to air-cooled engines, I believe that much could be accomplished by the use of composite cylinders using thick sections of aluminum to cool the combustion chamber and valves; this is based on my experiments at McCook Field with large bore, high compression aviation engine cylinders.

Regarding the carbureters, we have found by experiment that many existing carbureters fall far short of giving desirable air fuel ratios at certain throttled positions, and it has been found that this can be largely overcome, at least in aircraft use, by modifying the types.

GEO. E. A. HALLETT,
Captain, Air Service, Engineering Division,
McCook Field.

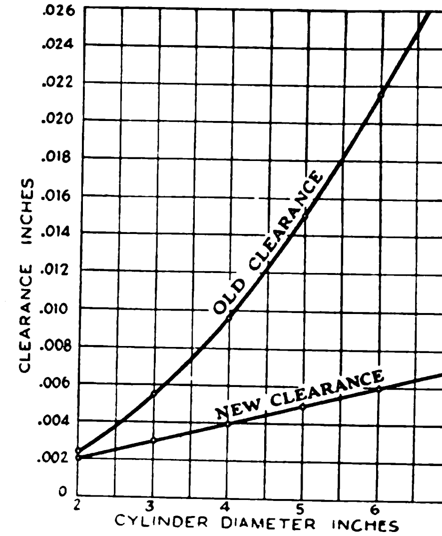


Fig. 4

Recent Developments in Aluminum Pistons

Editor, AUTOMOTIVE INDUSTRIES:

During the past year the aluminum piston has undergone a great development. The advantages due to the light weight and high heat conductivity of aluminum have long been realized, and aluminum pistons have been used with considerable success by many manufacturers. The casting in permanent molds, the development of a suitable alloy, the heat treatment of the castings are all developments of aluminum pistons of several years' standing. The one objectionable feature which has at times made trouble in the operation of aluminum pistons has been the fact that it was necessary to run them with a greater clearance than was the case with the cast iron piston. This was due to the greater coefficient of expansion of aluminum as compared with cast iron. In order to insure the best operation of an aluminum piston it is necessary that the skirt be fitted with as close a clearance as possible. The clearance of the ring lands makes very little difference as long as it is sufficient to prevent them from touching the walls of the cylinder.

Recent experiments have proven that the temperature of an aluminum piston skirt is not high enough to account for the amount of clearance which it has been necessary to give these pistons in the past. The head temperature, on the other hand, is much higher than that of the skirt. The expansion of the skirt may be divided into two parts: (1) the thermal expansion, that is, the increase in size due to the increase in temperature of the skirt; (2) the mechanical expansion due to the thermal expansion of the head, that is, the head being so much hotter than the skirt expands more, and this sets up a sufficient force to pull the skirt with it. It would be ideal to entirely separate the head from the skirt. Since this is not possible the next best thing to do is to separate the head from the skirt on the thrust faces only, and take care of the expansion in the direction of the pin by making use of a vertical slot or by relieving the piston on the side. Both have been successful. Fig. 1 shows a design embodying the vertical slot. When a vertical slot is used it must be placed on the low thrust side. Fig. 2 shows a piston in which only the head is separated from the skirt on the thrust faces and the expansion in the direction of the pin is made harmless by a relief. Fig. 3 operates in a similar manner to the piston shown in Fig. 2, but is not relieved to the same extent as the former. The extra clearance in the direction of the pin is obtained by grinding the piston oval, the shorter diameter being in a line with the pin.

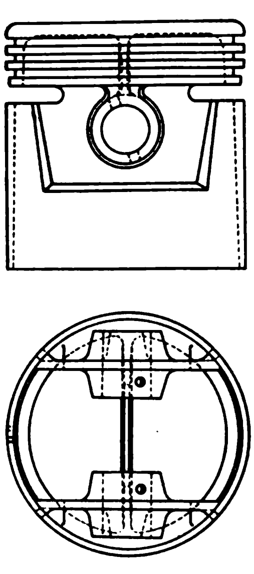

Fig. 1

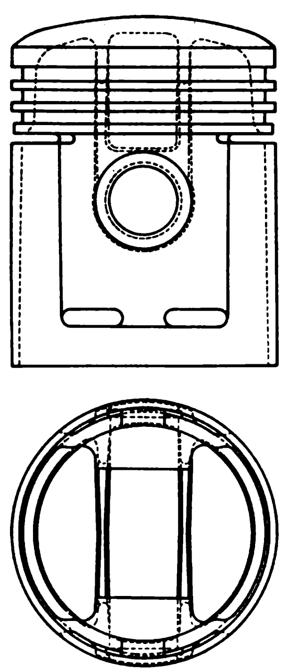

Fig. 2

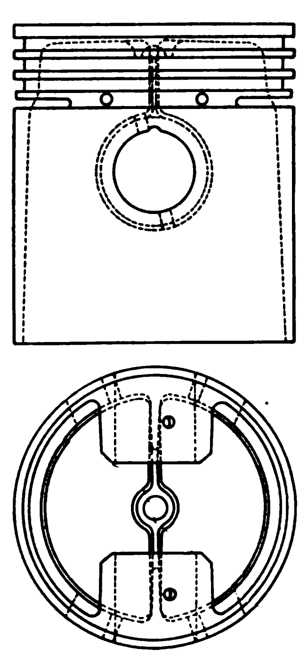

Fig. 3

Piston Clearances

All troubles of which aluminum pistons have been accused can be laid to the clearance. As explained above, this has been taken care of in the design of the piston. The curve of Fig. 4 is of interest, since it shows both the new clearance and that formerly required by aluminum pistons. The new clearance, which is the one to be used for all new designs, is 0.001 in. per in. diameter.

Oil Pumping

Experience has taught us that in order to eliminate oil pumping it is necessary that the relief on the piston pin side of the piston be either very generous and provided with a large outlet, or that the fit be made fairly close, just enough so the pis-

ton will not stick on these sides. Figs. 1 and 2 are examples of the large clearance on the sides, while Fig. 3 is an example of the latter type. The theory of this seems to be merely this: That we must either allow space for the oil so small that if all the oil passed into the combustion chamber it would be harmless or we must make it large enough so that the weight of the volume of oil will be greater than the capillary action and the oil will drain back into the crankcase rather than work its way up into the combustion chamber. It is very difficult, if not impossible, to draw a line between a clearance that is just large enough and one that is just too large. This can be determined only by experiment.

The slots separating the head from the thrust faces, besides making harmless the head expansion, must also function as a drain for the oil. As regards the former function the width of the slot is immaterial, but in order that it may act as an oil drain it is necessary that the slot be made of considerable width.

Wear

Piston wear is largely a function of piston material and of piston and cylinder finish. Aluminum pistons cast in permanent molds wear better than sand cast ones. If both the cylinder and piston have a smooth finish and the lubrication is ample, wear will be negligible. Of the several ways of finishing pistons and cylinders, grinding seems to be the best one.

FERDINAND JEHLE, Engineer,
Aluminum Manufacturers, Inc.

Use of Hollow Section Parts

Editor, AUTOMOTIVE INDUSTRIES:

There are many questions involved in the use of hollow section parts in an automobile, and each should be considered very carefully before proceeding to the general use of such a design.

The drilling of a hole in the center of a camshaft cannot be objected to from the standpoint of weakening the part unless the hole is extremely large or not machined accurately. In the writer's experience the use of such a hole has been more as an oil carrier than as a means of lightening the shaft. Rigidity is an important item in a camshaft, and it is also an advantage to have a camshaft as large as possible. The saving of weight is, of course, an item if the camshaft is extremely large, but the average shaft is of such a size that the drilled hole does not remove enough weight to make this a serious argument in favor of the drilled camshaft.

The drilled crankshaft presents several problems which should be considered very carefully. The elimination of weight in a rotating part, such as a crankshaft, is undoubtedly an advantage under most every condition. It is, however, extremely important that such drilled holes be accurately machined and as nearly concentric as possible with the finished bearings or crankpins, as an out of center condition will weaken the shaft at various points and may lead to considerable trouble if not watched carefully. Here, again, careful study must be made of the drilling of the crankshaft in such a way that the rotating weight will be removed and still not weaken the shaft to such an extent that vibration might result. To illustrate, the drilling of a large hole through the center of the shaft through all the main bearings might make that shaft subject to extreme twisting under stress, where the drilling of the same hole in the crankpin would weaken the shaft comparatively little and at the same time remove the weight desired. There is perhaps a best combination of crankshaft strength and reciprocating weights, and this should be determined, if possible, by careful experiment.

The use of tubing for propeller shafts is beyond any question a very good practice, and especially is this true due to the general use of seamless steel tubing which, of course, is accurately made as to the thickness. The elimination of weight in this part is further very advantageous, as it eliminates the whipping to a large degree.

The writer questions the advisability of using hollow axle shafts for the simple reason that the only apparent reason for such design is the elimination of weight. In order to make use of a hollow shaft, the shaft itself must be larger in order to obtain the strength desired, and the consequent larger bearings and the larger bearing retainers will more than balance the weight saved in the shaft itself. Furthermore, it is not possible to save any weight by drilling an axle shaft, excepting in the full-floating or semi-floating type of axle, where the outer end is large enough to allow the drilling of a hole in the center of the shaft.

Chief Engineer, Saxon Motor Car Corp.

Aircraft Engineering Ahead of Business Phases

Editor, AUTOMOTIVE INDUSTRIES:

Aircraft engineering is well ahead of the business of transportation by air. Apart from fighting machines, the engineer, be he plane or motor man, can only guess at the requirements. Of course, the greatest handicap to the extension of the use of airplanes is the necessity for extensive landing facilities. If, without sacrificing existing qualities, it were possible to produce machines which would rise and alight vertically or at an angle of 45 degrees, the use of aircraft would receive the greatest imaginable stimulus.

Because the landing difficulties are greatly increased, the writer is inclined to believe that the development of very large airplanes is premature. Ships cannot be built bigger than the available docking facilities. Aircraft of the present day are amply safe and are easy enough to fly, but on and near the ground they are still awkward, and such danger as is run in their use is almost wholly due to their poor maneuverability when in confined quarters. Of course, a machine which will move vertically or almost vertically has long been an inventor's dream. The writer believes that enormous improvements in engine and plane construction of the past few years have made the realization of this dream entirely possible.

A. LUDLOW CLAYDEN.

Cast Iron for Camshaft Bearings

Editor, AUTOMOTIVE INDUSTRIES:

Answering your communication of April 28 requesting opinion on current engineering problems, there are many which at this time are worthy of serious consideration. I will, however, confine my discussion to the question of cast iron camshaft bearings.

Cast iron as a material for camshaft bearings is unquestionably satisfactory. The relative merits of the bearing within the crankcase itself, as compared with a separate bushing, can only be logically discussed from the standpoint of service. There are no particular difficulties with the integral bearing with the possible exception that

adequate oil ways for the distribution of oil, particularly with splash feed, cannot be readily put in, and this may lead to a small percentage of scrappage as a result of the bearing seizing if the fits are not well maintained.

Considered from the viewpoint of service, it is, to my mind, necessary to provide replaceable bearings in any wearing part of the engine. This though we have carried to the extreme in the new designs of truck motors which we are now building, service and ease of replacement being of paramount importance.

The Engineering Side of Industrial Relations

Thoroughly Interested Workers

Editor, AUTOMOTIVE INDUSTRIES:

I have been very much interested for a good many months back in the series of articles contributed by Mr. Tipper on factory human relationship, management, etc., and feel that if these articles are read and thoughtfully assimilated, they cannot help but be beneficial to the manufacturing establishments of America.

Peak production is what all manufacturers are after, and to my mind one of the most important principles to be sought in securing it is the securing of active harmony and contentment in the plant.

Peak production can, of course, be obtained in several ways, one of these being the adoption of driving and possibly coercive tactics on the part of the Chief and sub-executives. Providing the chief and sub-executives have, collectively, enough mental power to more than offset the collective mentality of all the workmen, peak production can without a doubt be attained and kept up, just so long as the mental ability of the chief executive and subordinates keeps above the collective mentality of the entire lot of workmen.

The average workman, however, who works with his hands is just as much of a human being as the bulk of the executives, and if "the big club," or other coercive tactics are used, the workmen generally resent it and are continuously endeavoring to figure out some way of outwitting the bosses. If, on the other hand, the workmen can be convinced primarily of the absolute fairness of the executives and can be brought to the attitude of working with the bosses, instead of for them, it generally happens that the mental effort which the workmen have been putting into ways, means and methods of beating the executives to it, will be put in on ways, means and methods of increasing their productivity, with the result that peak production is secured through the combined willing effort of both the executives and the workmen.

There is no question, I believe, in anybody's mind but what the cumulative effort of a big mass of humanity, working absolutely together, is far better and more productive than the cumulative effort of one relatively small mass and another one relatively large, engaged in a tug of war.

I have visited, during the past fifteen or twenty years, a great many of the manufacturing plants and have a good many times run across some of the higher class workmen on the train, or in other places, who have sometimes been exceedingly free in expressing their opinion or opinions, regarding certain manufacturers, some opinions being very complimentary and others and for other manufacturers, being very much the opposite of complimentary. Without doubt some of the non-complimentary things said were not founded on actualities, but were due to a distorted vision or opinion, engendered by a virtual physical collapse due to the high pressure and long hour requirements of their particular manufacturing institution.

There is a limit to the number of hours during which a workman can put out the best that is in him. He will work longer hours, with less fatigue, if he is thoroughly interested, contented and satisfied, than he can if he is not. On the other hand, no matter how well interested, contented and satisfied he is, there are physical limitations to be taken into consideration, and from my own knowledge, based on experience, it would seem that somewhere between nine and nine and a half hours is the limit that the average contented individual can put in and at the same time give the best there is in him.

J. W. DECON,
General Manager,
Fairfield Manufacturing Co.

Men and Systems

Editor, AUTOMOTIVE INDUSTRIES:

I have read a number of Mr. Tipper's articles and have found them very stimulating and full of suggestions.

Mr. Tipper has evidently made a comprehensive study of the questions involved in manufacturing relations, and writes forcibly, clearly and intelligently concerning these problems. I have no doubt that, directly and indirectly, they have had a large influence in directing and moulding opinion.

The most important problem in all manufacturing and commercial relations is the human problem. System is necessary to efficiency, and, other things being equal, the business which is run on a well-thought-out plan will undoubtedly be most efficient; but no system, however efficient, will avail unless it is worked by men who are both capable and loyal; so that the question of most importance in any organization is the quality of its man-power. This applies all along the line, from the chief executive down to the least skilled employee.

Better industrial relations will be the result of better human relations. A part of the service rendered by Mr. Tipper has helped to make the above fact clear and has no doubt resulted in quickening and directing thought along this line.

C. H. LIPPINCOTT,
Manager, Co-operative Department,
Studebaker Corporation.

Following Leaders

Editor, AUTOMOTIVE INDUSTRIES:

Will you permit me a little space to express my highly favorable opinion of the articles of Mr. Tipper. Although I am not in the business, I have noted them for a considerable period and they seemed to me to invariably contain suggestions which have the ring of good common sense.

The situation which has developed between capital and labor is a thoroughly unnatural one. The contest, not necessarily acrimonious but preferably friendly, should have been between the several organizations making up a business, each unit of which would have been made up necessarily of component parts of capital and labor.

The vast majority of men seek for heroes and for leaders, and far from being hostile or jealous they are enthusiastic and ready to follow beyond reason and to accept less

than their due share in an enterprise in which all are concerned.

The attitude of organized labor to-day is the fruit of many years of a selfish and provocative attitude on the part of capital.

It would seem almost axiomatic that any organization whose employees from the lowest to the highest felt loyal to it, and a personal pride in its success must have the advantage over similar bodies whose employees regarded it as an alien and at times a hostile body. In such an organization there would not be the constant change of personnel and the consequent waste, and the concern would have the advantage of all the invention of which its employees might be capable.

To arrive at this result would seem to require no specially complicated process. Fair wages based on the ability to pay, a willingness on the part of those in control to make clear to their employees the justice of the wage scale and also the desire of the management to have the advice and suggestions of everyone connected with the business on all points where it could be helpful, an evident interest on the part of the management to secure the maximum well-being of all concerned, which would include a friendly settlement of the number of hours of labor, which might and probably would be different in different departments, on the theory that what produced the best results financially without undue fatigue was to the common interest of all, and perhaps, as much as anything else, an insistence by the management on that courtesy to everyone employed which recognizes the dignity of his fellow man.

There would seem to be no reason, at least with American workmen, why such a program should not eventually produce a working force heartily pledged to the success of the organization and with a feeling of loyalty to it which would carry it through lean years as well as years of success.

The presence in trade unions of a large number of workmen connected with organizations so managed would have a wide effect on the character of the union and an increasing number of organizations following such a program would force into line others who would find themselves unable otherwise to successfully compete.

There is nothing Utopian about the foregoing. The success of business in the United States as compared with some other countries is based on the ability of its business men to pull together and to repose confidence in each other in common enterprises, and there is no reason why an extension of the same admirable policy should not produce equal if not greater results when the executive heads of business and manufacturing enterprises make common cause with their workmen.

The automobile industry seems to be one of such great size that any attitude toward the labor problem which was taken up by it would have great influence in all lines of industry, particularly if it proved to be advantageous. The large majority of its employees are men of intelligence and more or less skill and might therefore be expected to respond more readily to a change of attitude as above suggested.

CHARLES E. MANIERRE.

Weight Factor in Truck Performance

Editor, AUTOMOTIVE INDUSTRIES:

It seems evident to me that the attainment of a substantial reduction in weight along with a sustained performance, that is reasonably good, constitutes the next logical step in design necessary to create economy and satisfaction in the hands of the user.

In its present stage the motor truck of two-ton capacity and under is, or has been, designed to meet solid tire requirements with relatively low speeds and the variation in weights of trucks of a given capacity are as high as 50 per cent. It is certainly very plain that an owner of an extremely heavy one and one-half ton truck cannot expect the mileage from his fuel and tires that can be had by an owner of a truck weighing 50 per cent less and having the same capacity. The problem then resolves itself into one of making the light truck maintain its initial performance and to stand up against abuse. Quite contrary to opinions occasionally rendered, it has been my experience that the advantage in this respect does not always lie with the heavy vehicle, especially not where a rather high operating speed is required. In this respect the element of flexibility in the general design seems to contribute much toward preventing fracture, whereas a design supposedly rigid is only relatively so and quite often center strains at a weak point and where safe stresses are exceeded.

In making a saving in weight, a sort of compound advantage is gained in that a lighter truck requires less maximum torque to accomplish a given activity which, carried further, means a lighter engine to do the work, and this makes possible again a saving in fuel and tires. Thus it is highly important that we get started around this circle in the right direction. This can be done by the use of high grade materials which do not always cost the manufacturer more, thanks to the difference in their weights, by taking advantage of the saving made possible by pneumatic tires. Simply applying pneumatic tires to a truck does not necessarily mean a saving in any respect other than probably in the maintenance of the truck; whereas if the many factors that are so much different where pneumatic tires are used are taken into consideration in designing the vehicle, many real advantages can be placed in the hands of the owner.

In the matter of performance it is, I believe, highly important to consider not so much a new truck in perfect condition as one which has been in operation for at least thirty to forty thousand miles. For instance, gasoline has changed sufficiently in the last three or four years to actually affect the fundamental design of engines that are required to operate at high temperatures and to produce maximum power. This at one stroke eliminates engines of a design dating back five years or more, with due respect to the merits of such engines.

The intake passages, lubrication system and combustion chamber forms have been particularly affected. Much importance is placed by the writer on the combustion chamber form, as it has been proven by experience that an engine of the older type once considered a very good engine will lose 50 per cent of its power under the above conditions when it has accumulated a deposit of carbon. Whereas an engine with a very compact form of combustion chamber and very good manifold, together with a modern lubrication system, with the same amount of mileage, and as nearly as possible the same amount of carbon deposit, loses less than 10 per cent of its power under the same conditions.

It will always be found that when the weight is decreased and the performance improved as outlined, the average operating speed with a capacity load will automatically rise and apparently without any ill effects on tires or economy.

FLOYD F. KISHLINE, Engineer,
Graham Brothers.

The Engineering Number

AGAIN we hand to you the Engineering Number of AUTOMOTIVE INDUSTRIES. We believe that this is the best of the series of Engineering Numbers and that a place exists for it. We hope that it will, to an extent, fill this place.

There are features of this number that are different from those of the past. Indeed, the entire character of the Engineering Number has changed since its inception. The editorial staff is guided by its sense of need, rather than by precedent. One feature to which we would invite your attention is the series of articles on design. We have covered here some points with which every design engineer is familiar, but we hope to have presented these in a new way—in a way that meets the present status of the industry. There is one factor in this series that is not generally considered in engineering, that is the importance of the human element in the factory to engineering practice.

Also, we would suggest that much good can come from a consideration of the Forum, which comprises an unusual presentation of opinions from men who rank high in automotive engineering. The industry cannot help but benefit when these men speak frankly and their opinions are given consideration. We hope that this expression of opinion will be continued. This is our invitation to you to carry on.

No attempt here is made to discuss the contents of this number. There are articles of research character and also original theory—something new and something old, and, we hope, something for good of the industry.

The Fuel Problem Still With Us

LET no one be deluded into thinking that the decline in price of gasoline during the past nine months is an indication that the fuel problem has been solved, or that the supply of gasoline at present prices will continue indefinitely with abundance regardless of demands. The price of gasoline, in common with other commodities, responds to the law of supply and demand, though for reasons known to the oil producers it did not increase in price as rapidly as other commodities or even other petroleum products during the war.

The demand for gasoline is controlled largely by the number of cars in operation and the average distance each car is operated. The number of cars in existence is increasing, though the use in the average case has been somewhat curtailed during the present period of business depression. For these reasons the demand for gasoline and, consequently, the production of this commodity has fallen off, but this is distinctly a temporary condition, and one which will change rapidly as conditions return to normal in the business world.

The need for building cars that are more economical in fuel as well as oil consumption and in other ways conserving the fuel supply of the country continues. In other words, the fuel problem is still with us, though temporary conditions may make it appear less pressing. Fortunately, much research looking toward its solution has been prosecuted or is in progress. A review of what has been accomplished and some suggestions for future research and development are contained in the lead article of this number of AUTOMOTIVE INDUSTRIES. We recommend that engineers and executives who have to do with the design and production of automotive apparatus study this article and the reports of investigations upon which it is based, with a view to comparing the performance of their own products with that of apparatus incorporating such improvements as the various experimenters quoted have found desirable.

It pays to pause occasionally and take stock of developments brought to light by others in similar lines of endeavor. Comparisons are not odious when we profit by the knowledge gained in making the comparison.

Those who have contributed to the sum total of information calculated to aid in solution of the fuel problem, as well as those who have supported, encouraged and made available in printed form the results of investigations in this line, are to be complimented. It is a striking tribute to the value of such institutions as the Society of Automotive Engineers, the Bureau

of Standards and the research departments of our modern industrial organizations. May the good work continue and its results receive the recognition they deserve in more general commercial application!

Outstanding Automotive Engineering Problems

WHAT are the chief problems that confront the automobile and truck engineer to-day? The question is particularly pertinent on account of the present depressed condition of business, which calls for the best efforts of every branch of the industry. The slump in car and truck sales is, of course, in a large measure the result of the general business depression, and can be relieved only in the measure that general business improves. But conditions in the automobile business have undergone a fundamental change in that we have reverted to a competitive basis, and hereafter every engineer will be called upon to do his very best in seeking to meet the demands of the purchasing public.

There are two outstanding problems that claim the attention of the engineer to-day. One is that of better adapting the vehicles or their engines to the use of grades of fuel now on the market, and the other that of reducing the operating cost, so as to enable more people to own passenger cars and to make it possible for the motor truck to compete more successfully with the horse on the farm and with the railroads in short distance freight haulage.

It is not necessary here to dwell at any length on the fuel problem; some phase of it is discussed in almost every issue of this paper, and its importance is fully recognized. On the whole, the fuel problem is not as pressing as the problem of economical operation, because our engines are being successfully run on the quality of gasoline now sold, and, as the stocks of this gasoline are increasing, there is no immediate danger of circumstances compelling a lowering in the quality.

On the other hand, the need for more economical operation is most urgent, more particularly as regards trucks and tractors. In the truck field we have come to a point where the largest apparent market is among farmers. The farm truck is a necessary complement of the farm tractor, for it is only by the acquisition of both that the farmer is enabled to dispense with his horses. But since last year there has been a great drop in the value of horses and a still greater drop in the cost of horse feed, hence the competition of the horse has become very much more severe.

To render automotive apparatus more economical both the first cost and the cost of operation must be reduced. In the endeavor to accomplish this result all the departments of the factory must co-operate. In the manufacture of trucks the most promising policy is undoubtedly that of standardization of models and quantity production. What possibilities this holds out in the way of lowering production costs is well exemplified by the best selling makes of low-priced passenger cars. Standardization and quantity production can be fully as well attained by the assembling plan as by production of the complete truck in a single plant. But in order that the highest economy may be achieved it is necessary that each assembling plant confine itself to one model. The "complete line," of course, has its appeal, especially to the sales department. Considerations of economical production, however, favor the single model, and, in a strongly competitive market, if the purchaser is offered a substantial share of the advantages resulting from standardization of product it should be easier to do a given volume of business with a single model than with a series of models.

The engineer's problem consists mainly in adapting the design of the vehicle to economical manufacture, as well as in designing for economical operation and maintenance. In the selection of materials of construction and of processes of manufacture he must not only keep in mind the functional requirements, but also aim at easy production. Great expectations are sometimes attached to the plan of using individual parts for two or more functions. There is no doubt that material gains often result from this practice, as the construction may be simplified and the weight reduced without serious sacrifice in operating efficiency.

One way by which the industry can be put on a basis of greater economy is by so standardizing parts as to facilitate specialization in their manufacture. Good examples of this plan are furnished by the standardization of wheel hub and truck chassis dimensions by the S. A. E. during the past half year. Truck wheels and truck bodies are practically always manufactured in specialized plants, and the standardization referred to aims at making wheels and bodies interchangeable on trucks of different make of about the same carrying capacity. It will, therefore, enable the firms in these lines to manufacture in quantity—in advance of orders, if need be—and thus cut down production cost.

Automobile development in the past has proceeded along rather conservative lines, and radical innovations have been few and far between. So far as passenger cars are concerned, we can hardly hope to greatly exceed the standards of speed, silence, comfort, flexibility and reliability that have been set by the best modern cars. About all we can hope to do is to make these qualities available at lower cost. Radical departures would be warranted only by extremely urgent demands for increased economy, because such radical changes as, for instance, the abandonment of the Otto cycle engine would undoubtedly involve sacrifices in the way of flexibility, silence and general handiness, and at the present time the great majority of buyers are not prepared to make such sacrifices. Any such radical changes are most likely to come by way of the tractor and truck—fields in which the requirements other than those of economy are less exacting.

THERE is an often used commercial sign which reads, "If you are not pleased tell us, if pleased tell your friends." The editorial staff of AUTOMOTIVE INDUSTRIES would like your opinion, be it favorable or otherwise, of this and other numbers.

Summer Business Outlook Is Good

June Sales Certain to Beat May Record

No Justification for Gloom—Price Stabilization Most Important Factor

By JAMES C. DALTON

NEW YORK, June 13—Justification is hard to find for the gloom which permeates the manufacturing end of the automotive industry at this time. Fundamentally, general business conditions are more stable and the outlook is more hopeful than for more than a year. Ultimate recovery in the automobile field is more dependent now on the general business trend than it has been at any time since deflation began.

The automobile business this month will be better than most manufacturers expect it to be. There is little doubt that June sales will equal those of May and they may approximate those of April. This will be true particularly in lines which have stabilized prices. The result will be, unless production in the last two months considerably outran actual orders, that factories will have to begin turning out motor cars again in a few days. Those which are producing may have to increase their schedules. That seems to be the outlook for this month.

July and August always are the dullest months in the year for the sale of automobiles. The reasons for this condition are obvious and everyone connected with the industry is thoroughly familiar with them. There is no reason to believe there will be any great deviation this season from the normal state of affairs. If there is any it probably will be on the side of an unusually good July business as compared with June.

September Outlook Good

August undoubtedly will follow the usual trend and there will be the perennial slump. Unless all signs fail, sales will pick up the coming of September, and by the middle of that month factory operations should be well under way. There is every reason to believe that general conditions will become steadily more stable and by that time they should be auspicious enough to warrant confidence that the automotive industry will have entered upon a long period of prosperity. There will be no tremendous leaps forward, but the volume of sales should increase steadily each month, with due allowance for the usual seasonal fluctuations and spasmodic ups and downs in different sections of the country.

By mid-September the South and the great agricultural sections of the Middle West will be coming into the market for motor vehicles. The outlook for the farmers and planters is brighter than it has been for months. They probably will not buy in the usual volume before the fall of 1922, but sales resistance among them will be broken.

If there is any lack of stabilization in the industry by that time it will be largely the fault of the manufacturers themselves. In this respect there is a growing feeling of alarm among the dealers, and they make no secret of their apprehension. There are hundreds of dealers who have lost friends and patrons because the makers of the cars they sell issued positive statements setting forth the reasons why it was impossible for them to cut prices and then, only a few days later, announced reductions. This action hurt in lines which had given no guarantees.

Price Cuts Had to Come

Only a month ago manufacturers in Detroit were professing indignation at any suggestion that it might be possible to cut prices. They were pointing to high material costs and unprecedented overhead. Yet everyone who had a real grasp of the trend of economic events knew that price cuts were inevitable.

Dealers are not crying for price reductions. They are vastly more concerned in having prices stabilized. If their manufacturers will take a firm stand on present prices and prove that they are giving value received, the dealers will be entirely satisfied. What they want is to get the price question settled one way or the other for a reasonable length of time so they can take their coats off and go to work without the feeling that they are perjuring themselves every time they tell a prospect there will be no further price adjustments.

The chief concern of far-sighted manufacturers and dealers at this time is that the industry will drift into a situation closely akin to a price war with reductions coming at frequent intervals. Such a condition would be fatal to business for months to come.

Cuts Must Be Genuine

If there are any manufacturers who feel they can make a comparatively small cut now, to be followed by another in the early fall if sales are not satisfactory in the meantime, they are their own worst enemies. They will be serving themselves and the industry best if they make NOW whatever price adjustments they intend to make in the comparatively near future.

Normal conditions never can be restored in the United States until prices are stabilized. This stabilization is approaching in many industries and it is the most encouraging sign of the times. It is what the automotive industry needs

(*Continued on page* 1352)

Sales Continue High in Price Cut Lines

Metropolitan District Finds Prospects in Buying Mood—Deliveries Running Behind

NEW YORK, June 11—There are a good many indications that the New York territory will have a good passenger sales record for June. There is still considerable confusion and some distrust in the public mind over price reductions, but there is increasing evidence that buyers are inclined to accept cuts already made as representative of present day values, based on material and labor costs. Several cars which have had substantial price reductions since the first of May are selling so strongly that the total sales record for May and June will be decidedly respectable, despite the fact that a few of the uncut lines are having a hard time of it.

This week ended with Buick, Studebaker and Dodge Brothers leading in day-to-day sales. Buick and Studebaker have both been selling strongly and their price reductions served to prevent any falling off in business as a result of cuts in competing lines. Dodge had been selling indifferently for some time and dropped off materially when Buick reductions were announced. Then, when the Dodge reduction came this week, sales jumped skyward, and daily sales of the last half of the week are far ahead even of the records made when the Dodge car first made its appearance in New York.

Business Follows Reductions

Marmon, Jordan, Franklin, Oakland, Maxwell, Chevrolet and Ford have had good business since their announcement of recent reductions, and several other cars whose sales picked up, though not so noticeably, are still doing better than they were in May. Several cars which announced price reductions early in May have dropped off considerably from the sales spurts which immediately followed the cuts, but business is better than it was early in the spring.

Salesmen are finding some prospects reluctant to buy because the multiplicity of price reductions spread over a considerable period has created in their minds an impression that still further reductions may be looked for on cars already cut. However, these people are not in the majority.

Studebaker and Buick are both behind on deliveries and some orders have been cancelled and have gone to dealers in other cars, because of this fact. Several other lines also are short of certain

Factories Oppose Direct Truck Sales

Leaving Out Dealer Declared Bad Policy

Sales Manager Resolution Condemns Practice—Satisfactory Service Impractical

DETROIT, June 13—Voicing unqualified disapproval of the factory to consumer plan of selling motor trucks, directors of the National Association of Motor Truck Sales Managers, meeting here, adopted resolutions pledging aid and cooperation for dealers and efforts to discourage development of the direct sale plan. The attitude of the directors was unanimous, according to Don F. Whittaker, executive secretary of the association. Adoption of the resolution came after the resignation of W. N. Ackerman as director and the Lewis Hall Motors Corp. as a member. Ackerman is general manager of the corporation.

The sales managers declared they are concerned with the interest of the dealer as well as the consumer, the former in seeing that he gets a legitimate profit and the latter prompt and efficient service. The directors took the position that manufacturers, confronted by sales resistance, should endeavor to overcome adverse conditions by readjustment of distribution and dealer organizations and rejuvenation of their sales system rather than by destroying dealer organization and eliminating the real point of contact between the manufacturer and consumer and attempting to operate direct from the factory.

Fred Glover, general manager of the Timken Detroit Axle Co., G. W. Yeoman, vice-president of the Continental Motors and others were invited to address the meeting and presented their views. Following the lengthy discussion, the resignation of Ackerman and the election of J. F. Bowman, sales manager of Garford to succeed him, the resolution was adopted. It provides that:

Would Keep Tried Methods

"Whereas certain procedure has promoted the best interests of manufacturers and certain sales policies have shown tangible and definite results, the association will not indorse or approve any sales and service plan which will take from motor truck dealers profits to which they are entitled, realizing that such methods ultimately will be to the detriment of the consumer in that they will seriously affect proper servicing."

The resolutions further declare that the association will aid and support dealers in efforts to give prompt and efficient service, possible only through direct contact between dealer and consumer, and will discourage the factory to consumer method of merchandising trucks in the belief that the plan is impractical in that satisfactory service cannot be rendered without resulting in injury to the industry and great detriment to interests of dealer and consumer.

The development of plans for standardizing location of truck chassis numbers to prevent fraudulent practices of unscrupulous persons in dealing with finance companies, the determination to investigate the used car clearing house with a view to advocating its extension all over the country is shown to be successful and plans for giving further assistance to the National Automobile Dealers' Association in securing the united support of truck dealers and full cooperation in eliminating improper sales and discouraging sales to persons not financially responsible, were taken up and acted upon following action on the direct selling plan.

Hall Official Asserts "Sales Not Camouflaged"

DETROIT, June 13—After receiving from the board of directors of the National Association of Motor Truck Sales Managers a note informing him that they had adopted a motion "protesting against indiscriminate selling of motor trucks to fleet owners direct from the factory," W. K. Ackerman, vice-president and general manager of the Lewis-Hall Motors Corp., sent the following reply to Don F. Whittaker, the executive secretary:

"Yours of the 11th ultimo, 'PROTESTING AGAINST INDISCRIMINATE SELLING TO FLEET OWNERS AT A DISCOUNT AS BEING THOROUGHLY SUBVERSIVE TO THE BEST INTERESTS OF THE MOTOR TRUCK INDUSTRY' and requesting that such policy be discontinued, received. In reply, would state that, inasmuch as the policy of selling direct to fleet owners has been definitely decided upon by us and will be continued by us, not indiscriminately, as you state, but with due respect to the prospects' standing, the only graceful procedure on the writer's part is to tender his resignation, for immediate acceptance, as one of the board of directors and to discontinue this company's membership to the N. A. M. T. S. M.

Sales Efforts Like Others

"This company and the writer are proceeding along sales efforts not unlike other manufacturers, the only difference being that we are not camouflaging our dealer in any way, yourselves nor ourselves, and have been frank, honorable, above board, and in the open in our efforts so as to in no way represent ourselves to our associates in any way other than what we really are. As to

Carolina to Impose Tax on Car Makers

Will Assess Manufacturers, Resident and Non-Resident, $500 Under 1917 Act

RALEIGH, N. C., June 13—The State license tax of $500 on manufacturers of automobiles stands in spite of the opinion of the United States Supreme Court to the effect that Section 72 of the North Carolina revenue act of 1917, relating to the tax, is unconstitutional. This is the opinion of State Assistant Attorney General Frank Nash, after learning of the Supreme Court decision.

The 1917 act contained two provisos, making the tax only $100 on certain manufacturers. Those that came under the provisos were manufacturers paying taxes on plants in the State, and those that invested three-fourths of their assets in State bonds, or municipal bonds of the State.

These two provisos the Supreme Court held unconstitutional as discriminatory against non-resident manufacturers. Anticipating such an opinion as a possibility, the Legislature of 1921 incorporated a provision in the revenue act that if any part of any clause or section of the revenue act should be declared unconstitutional the remainder of the clause or section should remain in force. Under this provision the decision then simply has the effect of raising the tax on the State manufacturers to $500, and not of nullifying or lowering the tax on outside manufacturers.

Suit which resulted in the Supreme Court decision was brought by the Bethlehem Motors Co. and the National Motor Car & Vehicle Co.

Greenfield Tap and Die Buys Machine Plants

GREENFIELD, MASS., June 14—Directors of the Greenfield Tap & Die Corp. have voted to purchase the entire capital stock of the Greenfield Machine Co., manufacturers of cylindrical and universal grinders, and the Morgan Grinder Co. of Worcester, Mass., manufacturers of internal grinders. These two companies, together with the machines now produced by the purchasing company, will constitute the machine divisions of the Greenfield Tap & Die Corp. Both plants will be operated as at present.

There will be no changes in the organization of the plants. Ralph L. Morgan will continue as president and Charles E. Hildreth as general manager of the Morgan company, and E. F. Smith as president of Greenfield Machine Co.

Chandler at $1785, Back to 1913 Basis

All Open Car Models to Sell at Old Price—Cleveland Also Cut

CLEVELAND, June 13 — Chandler Motor Co. made sweeping price reductions here to-day that placed the Chandler price at $1,785, back where it was in 1913. At the same time the price of the Cleveland which is made in a factory where there is much Chandler money, was cut to $1,295.

The Chandler company up to the present had continued prices which it said were warranted by improvements made in the car since 1913. The price reduction coming at this time, is to increase production and to stimulate interest in the two cars.

The 1913 5-passenger Chandler sold at $1,785, the 1921 7-passenger touring car, effective at once, is selling at the same figure. The car has been constantly developed in the last eight years. It also has been enlarged and refined and the management said that the car of to-day would have sold for twice its present price in that earlier day. Production methods and scientific management enables the company to put the improved car on the market at its present price.

The Chandler schedule of prices follows: Seven-pass. touring, $1,785; 2-pass. roadster, $1,785; 4-pass. roadster, $1,785; 4-pass. dispatch car, $1,865; 7-pass. sedan, $2,885; 4-pass. coupé, $2,785; limousine, $3,385.

The price of the Cleveland on Sept. 1, 1920, was $1,645. The new price effective at once is $1,295 for both the 5-pass. touring car and the 3-pass. roadster. The 5-pass. sedan will sell for $2,295 and the 4-pass. coupé for $2,195.

COLUMBIA BATTERY REDUCED

CLEVELAND, June 13—The National Carbon Co. has put into effect a reduction of approximately 20 per cent on Columbia dry batteries. The price cuts vary somewhat in different sections of the country because of freight differentials but 20 per cent represents a fair average of the cut.

COMMERCE PRICE GUARANTEED

DETROIT, June 16—The Commerce Motor Truck Co. has notified its dealers that present prices on 1921 models of Commerce trucks are guaranteed for the remainder of this year and that if any changes are made before Jan. 1, rebates will be given either to dealers or purchasers.

CITY BANS ASSEMBLED TRUCKS

NEW YORK, June 16—Manufacturers of assembled trucks are awaiting with much interest the result of an inquiry into the purchase of trucks by the city last year which will be made by the legislative committee investigating municipal affairs. It is understood that when bids were asked on these trucks it was stipulated that "it is the intention of these specifications to describe what the city terms as a manufactured and not an assembled gasoline motor driven truck." It was stipulated that any company bidding must have in operation in the United States at least 100 trucks each of which had run 75,000 miles and that it must have a parts stock in New York valued at not less than $60,000.

15,000 Orders Ahead at Willys Factories

TOLEDO, June 15—John N. Willys, president of the Willys-Overland Co., here to-day with Vice-President Walter P. Chrysler to attend a banquet tendered to Vice-President Charles B. Wilson by former associates from Pontiac, Mich., declared that the factory here is being flooded with orders by dealers in all parts of the country.

Willys said there were 15,000 unfilled orders on hand now and that preparations were being made to put on extra shifts to turn out the cars.

Scripps-Booth Adds Six-Cylinder Line

DETROIT, June 13 — Scripps-Booth has added a new six-cylinder model to the present line, this being equipped with a Continental Red Seal 7R engine, 3¼ x 4½ in. The prices of the present model B series, which will be continued, and the new model F series, follow:

	F Series	B Series
5-passenger touring	$1,490	$1,295
3-passenger roadster	1,470	1,275
5-passenger sedan	2,375	2,100
4-passenger coupe	2,350	1,950

The new model ranges from $195 to $400 higher than the present model. Production of the new model is under way and demonstrators are being delivered to dealers this week and next. Among the other specifications are: General Motors approved axles, Borg & Beck clutch, 7-in. frame, 115-in. wheelbase, 32 x 4 cord tires.

BUICK TO BRING OUT "FOUR"

DETROIT, June 10 — In connection with the Buick announcement of its revised prices, attention has been called to the fact that no changes will be made in the sixes for 1922; that is, the 1921 series will be carried through the 1922 season without any changes whatever. The Buick company, however, will announce a four-cylinder car in August.

TRUCK RECEIVER APPOINTED

NEW ORLEANS, June 14—Motley Lewis of the A. M. Lockett Co. has been appointed receiver for the New Orleans Motor Truck Mfg. Co.

White Truck Prices Reduced $200 to $500

Five Ton Model at $4500 Back to Pre-War Rate—Others Virtually So

CLEVELAND, June 13—Price reductions on all models of White trucks, effective immediately, put the 5-ton model back to the 1914 price and other White models so close to the pre-war figures that, the company declares, in view of improvements to the product, they also are virtually at pre-war levels.

Following are the revised chassis prices f.o.b. Cleveland.

5 ton	$4,500,	was $5,000
3½ ton	4,200,	was 4,500
2 ton	3,250,	was 3,450
¾ ton	2,400,	was 2,600

WILSON TRUCK CUTS PRICE

DETROIT, June 13—A substantial reduction in the prices of all models of Wilson motor trucks is announced by the J. C. Wilson Co. Four sizes of trucks are made by this company and the reductions in prices range from $380 on the 1½-ton model to $755 on the 5-ton truck. The new and old prices follow:

	OLD	NEW
1½ tons	$2650	$2270
2½ tons	3300	2825
3½ tons	4300	3685
5 tons	5275	4520

These price reductions go into effect at once.

HARVESTER TRUCK DOWN

CHICAGO, June 11—The International Harvester has cut prices on its heavy duty motor truck as follows: One-ton truck from $1,850 to $1,750; 1½-ton $2,050 to $1,850; 2-ton truck from $2,400 to $2,100; 3-ton truck from $2,800 to $2,400; 5-ton truck from $4,500 to $3,600. A 25 per cent reduction on cab bodies, tops and other accessories is also announced.

BESSEMER TRUCK CUTS PRICE

GROVE CITY, PA., June 10—Price reductions ranging from $400 to nearly $1,000 are announced by the Bessemer Motor Truck Co. The 1-ton truck has been reduced from $1,700 to $1,395; the 1½-ton from $2,445 to $1,995; the 2½-ton from $3,285 to $2,595; and the 4-ton from $4,485 to $3,495. Prices are f.o.b. factory.

GARFORD PLANT COMPLETED

LIMA, OHIO, June 13—The Garford Motor Truck Co. has completed a modern progressive assembly plant and office building. The new unit brings the factory floor space up to 14 acres and will more than double the production capacity. The building, two stories high, is constructed of concrete, steel and glass. The assembly division is 420 ft. x 100 ft.

Exchange Drop Halts Sales to England

Progress Toward Equalization of Rates Set Back—British Seek Tariff Protection

LONDON, May 30 (By Mail)—Up to the time of the most recent slump in sterling exchange, the gradually ascending value of the pound, as expressed in dollars, was evening up conditions of competition and restoring the American car and tire import trade to something like pre-war times. The 33 per cent tariff on imported cars is likely to be continued for some time, but he would be a bold man who would predict its duration. A very strong undercurrent of opposition to the anti-dumping legislation makes its passage far from certain. The principle of production never has been presented to the electorate for a vote.

A renewed effort is being made to have tires included in the import tariff, and to that end propaganda is being carried on by the British Rubber Tire Manufacturers Association, Inc. Some of the fallacies contained in a booklet prepared by the association are too apparent to need comment. In fact, the argument fails at its source because in the main, apart from certain inaccuracies in quoting exchange rates and in statements on wages in the foreign tire industry, it lumps the import trade as a whole and does not differentiate between the favorable conditions of the exchange as it concerns the American tire importers and the very unfavorable state of the exchange for the European tire importers to Britain.

So far as the British automobile trade is concerned, the trend is steadily toward even lower prices. About 90 per cent of the cars on the market are down from 20 per cent to 25 per cent on the February rates. This does not take into consideration the American "sixes" and large "fours" which have slumped badly and have been cut to almost clearance rates. The downward trend is likely to be continued because of the reduced cost of materials and lower wages. The wage factor should be a ruling one because it was used to justify the advance in prices, and the argument must react under the present conditions.

Demand for Economy Cars

Moreover, the trend is certainly toward lighter cars, that is cars lighter on fuel and tires but not "light" in the category of runabouts weighing in the neighborhood of 1000 lb. This latter class is taboo to the real motoring public. This includes the family man who needs a roomy car at the price of a Ford, but not a copy of it. Such a car would sell at $1,500. One selling at $1,250 would find a good market even without the starter and certain embellishments.

The middle priced car seems to be passing out of vogue here, possibly with the result of increasing the number of top grade cars. In this connection it is interesting to note that one of the super-British cars is likely to lose some of its best customers for the reason that profiteers and newly rich are rushing into the market for this make, and as they come in the British gentry goes out. As a consequence, it is stated, certain high grade French cars, which had a small sale before the war, are again in demand by the "old rich." Certain high grade American cars are sharing this field.

Much interest has been aroused here by the decision of Angus Sanderson dealers to subscribe $185,000 toward the fund needed to refinance the company. This would be only a fraction of the new money necessary, but the offer of the dealers denotes the trend toward co-operation between the manufacturing and sales trade.

It is held that the dealer who has a monetary stake in the production of a car has a greater natural incentive to push sales than his neighbor who is only a dealer first and last.

British Make Bid for Canadian Farm Market

NEW YORK, June 13—Increased production of British agricultural machinery and tractors through the cultivation of foreign markets is being urged in England as a means of bringing prices to a level that would permit successful competition with foreign-made products, according to information just received from London.

In this connection, the report says, arrangements have already been made to produce one well-known British tractor on a large scale and market it in Canada on a systematic plan. Canada is the world's largest market for tractors, and up to the present it has been practically controlled by the United States, and the selling scheme of this British tractor will be planned especially to meet American competition.

A branch factory will be established in Montreal with an adequate stock of spare and repair parts, and special arrangements will be made for service, a factor which has been more or less negotiated by British firms in the Canadian market.

British Apathy Losing South American Market

LONDON, May 27 (By Mail)—A South American correspondent of the (London) Times Trade Supplement sounds a warning to the British automobile trade concerning the race for the South American market. He says local republics complain of British apathy and contrast it with live methods of Germans and Americans. Brazil imported last year 24,475 cars of which Britain sent only 586. Venezuela and Chile says the same and both want automobiles. Venezuela in particular wants motorcycles. The Argentines want trucks and farm tractors capable of hauling four, six and eight plows.

Paris Show Requests Exceed Palais Space

Exhibitor List Far Exceeds Former Figures—American Cars Get Space

PARIS, June 4 (By Mail)—More than 800 applications have been received for space in the French automobile show which will be held in the Grand Palais from Oct. 5 to 16, this constituting a record, for previous shows have only united between five and six hundred exhibitors. Not only is the number of firms higher than usual, but the amount of space requested breaks all records, being so great that the Grand Palais, which is believed to be the biggest building in the world under a single roof, has become insufficient. As the management has need of about 3500 square yards of additional space, it is probable that two buildings will be used.

It is not known whether an existing building can be found, or whether a temporary building will be erected on the Esplanade des Invalides, which is only separated from the Grand Palais by the bridge across the River Seine. Probably trucks and agricultural tractors will be put in the overflow building, thus leaving the Grand Palais for passenger cars and automobile accessories.

The Paris show is widely international, and will comprise all but late enemy manufacturers. Although American firms do not get first choice, they will be well represented, and all the firms united in General Motors will have stands. The Paris Show management objects to the report circulated in America to the effect that Americans are shut out of the Paris exhibition. It is pointed out that while American firms are made to select positions after European makers, they are always assured space on the floor of the main hall. This, it is declared, is in contrast to the policy of New York and Chicago shows, in which foreign firms cannot exhibit.

The Paris international exhibition will be preceded by a national show at Berlin from Sept. 23 to Oct. 2, and will be followed by the London show in November and Brussels show in December.

TO FLY MAILS TO BAHAMAS

WASHINGTON, June 13—Providing a subsidy of 5000 pounds sterling per year for the purpose of carrying mails between Nassau, Bahamas and Miami, Fla., an act has passed its first reading in the Bahamas House of Assembly by which concessions are given to the Bermuda & West Atlantic Aviation Co., a British limited organization with registered offices in London. Advice to this effect has been conveyed to the Bureau of Foreign and Domestic Commerce through Consul Lathrop. It is expected that the hangar and repair shops constructed by the company will be open to the airplanes of all nations on reasonable terms.

Cuban Sales to Open in Coming 6 Months

Look for Biggest Automotive Year in 1922—Sugar Crop Brings Improvement

NEW ORLEANS, June 13—Movement of the new sugar crop in Havana, and a general clearing of the entire commercial and financial horizon throughout Cuba, has worked great improvement in the automotive industry in that island, according to Julio R. Bannatyne and Julian Fierros, president and treasurer of a large automobile and accessory selling company in Havana.

"The automotive industry in Cuba," said Bannatyne, "was one of the first to begin its recovery from the period of depression in business from which the island has been suffering for about eight months. Trade in general is becoming more active, but we, as well as we thought we knew conditions, were surprised at the rapidity with which the automobile, truck, tractor and accessory sales 'picked up' at the first indication of general commercial and financial improvement.

"I do not mean to say that normal business conditions have been restored, but the movement of the new sugar crop and the easing up to some extent by the banks on loans, has made money easier. The Cuban planters seem to realize fully the great aid offered them by the use of trucks and tractors, and the increased efficiency in business they get from passenger cars, so that much of the first money received for the sugar crop went into extensive purchase of automotive vehicles.

"All business, including the automotive industry, is being conducted on sounder, more conservative lines, and is establishing itself on a more substantial basis than it had before, so that in reality a great benefit accrued to all commercial undertakings in Cuba as a result of the period of depression, and especially to the automobile-selling industry, which, for some months of prosperity prior to the depression, simply 'ran wild.' We look forward to the last half of 1921 as much better than the first half, and to all of 1922 as the best year we ever have had in the automotive industry."

Philippines to Impose Special Taxes on Cars

NEW YORK, June 13—Every person engaged in the importation or manufacture of passenger cars, motor trucks, tires or parts will pay an annual tax of 20 pesos and a sales tax of 5 per cent if a bill to be presented in the Legislature of the Philippine Islands next October becomes effective. This bill evidently is based on Title IX of the United States Revenue Act of 1918, including virtually the same provisions.

The principle of Title IX, however, has been recognized by the U. S. Senate as being based on war conditions. Senator Penrose, the chairman of the Senate Finance Committee, in the hearing on May 23, 1921, said:

"There are several witnesses here to-day who want to be heard on the so-called sales or luxury tax. Perhaps this is hardly the time to discuss this matter, as the committee is very familiar with all of the arguments from the consideration of the last revenue bill. Of course, the gentlemen called upon to pay these taxes were prompted by patriotism and the desire to win the war, which in these times of peace do not exist, and many of them very properly and fairly desire to be relieved."

Australian Tire Market Reported Overstocked

WASHINGTON, June 13—The Australian market for tires is heavily overstocked, writes Trade Commissioner A. W. Ferrin. Two large Australian factories which now supply over half of the demand are contemplating an expansion which they claim will enable them to make all the tires Australia requires. All tire companies, including American, have cut prices. The new tariff imposes a duty of 40 per cent on pneumatic tires, while the loss in conversion of Sterling into dollars gives an even higher protection of local tires. Some believe that the importation of tires into Australia will eventually cease and that the only solution is to establish branch factories in Australia, to escape the burdens imposed on the imported tire. It is stated to be the expressed intention of the Australian government to encourage foreign manufacturers to establish Australian plants in the interest of Australian labor.

Berliet Continues Work Pending Tax Decision

PARIS, June 1 (By Mail)—The Berliet Automobile Works at Lyons, France, are not closed down, as a cable report having appeared in AUTOMOTIVE INDUSTRIES might lead readers to suppose. According to a communication received from the Berliet company, this firm applied to the French courts for the benefits of the law providing for transactional arrangements. This is a kind of moratorium for firms in temporary financial difficulties by reason of the transfer from war to peace conditions. This moratorium was necessary pending the settlement of a dispute with the French inland revenue authorities in reference to payment of the excess war profits tax. In the meantime the Berliet factory is continuing in operation and is producing passenger cars, trucks and tractors.

LITTLE RECEIVER RESIGNS

DALLAS, TEXAS, June 13—R. C. Ayres has been appointed receiver for Little Motor Kar Co., succeeding Everett S. Owens, who resigned. Judge W. F. Whitehurst said assets were about $200,000 and outstanding stock $1,000,000.

Australia Looks for Good Selling Season

Emergence from Drought Brings Optimism—Goods in Warehouses Retard Business

SYDNEY, AUSTRALIA, April 30 (By Mail)—The motor car industry in Australia is optimistic that the approaching season in Australia will be a good one, this optimism being based on the fact that for many years it was proven that after a long severe drought, such as Australia is just emerging from, there have been 3 or 4 good years in succession.

With such a prospect of the future it is possible for a perceptible improvement to take place in the next 6 months. Industrial matters in Australia will take a turn for the better. The prolonged shipping strike which has been an annual affair for the last 3 or 4 years, has turned out so badly for the strikers that it may be many years before they think of precipitating a similar situation.

The coal situation is improving and developments in many industries are encouraging. In the steel industry two large companies are getting into full operation. The rubber mills are at capacity. Australian wool is still unsold, but there is hope of getting rid of a large percentage of the last wool clip at a moderate price. A certain section of the agricultural territory has money available for the purchase of automobiles, but they are holding off in anticipation of a fall in price.

Unfortunately the Australian banks are short of money due to the heavy importations that have been made in many lines, as well as automobiles, and the banks blame this for the present money shortage. Importations were so heavy in the first 7 months of 1920, and prices so high, that great volumes of funds have been tied up. The following figures give some conception of this: Thus in textiles the importations in the first 5 months of 1920 were $135,000,000, as compared with $35,000,000 in the corresponding 5 months of 1919.

Imports in 1920 Heavy

In a few other industries the figures for these periods are: Machinery, including automobiles, $72,000,000, as compared with $43,000,000; rubber goods $9,000,000 as compared with $4,000,000; manufactured goods of wood $15,000,000, as compared with $4,000,000, glass and earthenware $7,000,000 as compared with $2,000,000; paper $16,000,000 as compared with $8,000,000. Thinking in totals this makes $360,000,000 of imports in the first 5 months of 1920 as compared with $165,000,000 in the corresponding months of the previous year, or a difference of $200,000,000.

The banks have had to finance these imports and are naturally compelling importers to restrict their operations from abroad until such time as the present goods in warehouses valued at $200,000,000 have been turned into cash.

June Sales to Equal Early Spring Months

Falling Market for Business to Continue for Long Time—Buyers Study Values

(*Continued from page* 1346)

more than anything else. There are many persons who are able to buy and want to buy who will not buy unless they are convinced they can't get the goods they want considerably cheaper in the near future than they can now.

All forecasts of prosperity for the automotive industry must be predicated on the understanding that there will not be periodical price revisions. Business will be done on a falling market for a long time to come, and the retail prices of automobiles will gradually decline, but there is no sense in readjusting them oftener than once a year. When readjustments are made there should be concerted action by the manufacturers, and the atmosphere should be cleared in a fortnight rather than have the period of uncertainty continue for two or three months, thereby unsettling trade.

It should be remembered, also, that purchasers are giving greater attention to values than they have in the past three or four years. They want their money's worth, and the manufacturer who can convince them they are getting it will do a better business in the long run than the competitor who cuts prices and takes value out of his product.

Plants Hold Output Close to Actual Sales

DETROIT, June 13 — Employment figures for the last week show an increase of but 124 men over figures for the previous week in 79 industries in Detroit, including practically all automobile plants. Twenty-seven factories are operating on reduced schedules, employing 20,312 men an average of 31 hours a week.

The employment situation in the State as regards automotive plants is not as bad as in Detroit. Good business and splendid prospects are reported by the Michigan Brass & Iron Works at Lansing in a statement by T. E. Hackett, secretary-treasurer. The plant now is on a 55 per cent production basis and everything points to an increase shortly.

The Lansing Foundry Co. at Lansing has resumed production on a 40 per cent normal basis following a long period of inactivity. Many orders and inquiries are being received from all parts of the country, new employees have been taken on and plans are being made for steady increase in production and employment during the summer and fall. The plant was closed entirely from Nov. 1 to May 1, and since reopening conditions have improved steadily until the last week it was decided to begin operation on a 40 per cent basis.

Olds Motor Works turned out 142 automobiles last Friday, and daily shipments from that plant are averaging around 125, according to Sales Manager Peasley. The Olds plant still has some orders ahead and will continue on the present schedule between 125 and 150 cars a day indefinitely, according to officials.

Buick and Chevrolet plants at Flint and the Oakland factory at Pontiac are speeding production to meet a sharp increase in demand as the result, factory executives say, of the price cuts. Officials admit frankly the sudden spurt represents an accumulation of orders due to determination on the part of buyers to sit steady until the reduction expected on the car of their choice. Some manufacturers incline to the belief that rumors of price cuts, even before the first announcements, demoralized the market and stopped buying at a time when the normal spring business should have been at its height, and predict a steady demand throughout the summer.

Study Territorial Markets

Factory and sales executives are keeping their ears close to the ground and representatives are touring the various sections of the country seeking to get a definite line on actual conditions that will permit of some definite manufacturing policy. Caution is the watchword and none of the companies are going to be led astray by the present rush of orders reaching nearly all plants. It will be the policy to steer close to shore and confine production schedules to actual orders from dealers based on a careful analysis of their individual territories and their probable requirements from week to week.

Sales Continue High in Price Cut Lines

(*Continued from page* 1346)

models and there have been some cancellations, the public showing little patience with delays when it is possible to obtain a second or third choice car.

Reports from the motor vehicle office of the Secretary of State at Albany indicate that the April sales figures will prove much larger than was expected when the month ended. Compilation of registration is always considerably behindhand and there was a big rush of registration during the last ten days of May. It was said to-day that the May sales record for ten counties in and around New York, which, it was thought, would fall considerably below April probably would equal it and might exceed it. It was also reported from Albany that registrations so far in June were running ahead of any other June in the history of the department.

TOOL PRICES GUARANTEED

BALTIMORE, June 13—The Black & Decker Mfg. Co. has notified its distributors that present prices are guaranteed until the end of the year. The company states that the total increase in the prices of all its products since 1914 has been only 38 per cent.

Ford Records Fall in Production Drive

All Departments Working at Highest Capacity — Knock-down Shipping Now Used

DETROIT, June 11—While the Ford plant is breaking records with startling frequency in the matter of car and truck production at Highland Park and the assembly branches, the body plant at River Rouge is busy and to-day is turning out about 1200 sedan and touring car bodies daily. About 2000 men are employed and it is significant that the time per job now is much less than when the body output was less than half what it is to-day, due to increased labor efficiency. The daily average for sedan bodies was increased 24 in May over April, averaging 254 for the greater part of the month. During the same period the output of touring bodies averaged 964, approximately 141 average daily increase in May over April.

The Highland Park plant is absorbing about one-quarter of the daily output from the Rouge body plant, and with the continued daily increase in production, it is expected the body plant soon will be running close to car production at Highland Park. Sedan bodies are being shipped to Des Moines and Kearny, N. J., assembly plants, as are also some touring bodies. Knock-down bodies are being exported to France, Denmark and England.

In shipping, an average of 140 to 170 knock-down touring car bodies are carried in one freight car according to variation in the size of the car. An average freight car accommodates about 110 knock-down sedan bodies. These bodies are complete ready to be assembled, painted and trimmed. Heretofore shipments were made by placing about 6 built-up bodies in a car. Conservation in shipping space and more efficient loading by means of knock-down methods has increased the car capacity from 6 to more than 100.

June Holds May Schedule

All departments of the Ford company are working full time—three eight-hour shifts—and there are to-day 43,000 men on the Ford payroll. Highland Park, during May, turned out an average of 4032 cars daily, and that will be kept up through June. On May 11, 4096 cars and trucks were turned out and six days later a mark of 4107 was reached. May 20 a new high mark of 4144 was made. This made the eighth time in 20 working days that production records were broken.

Of interest in connection with Ford activities is the remarkable increase in demand reported from the Ford branch in Halifax, Nova Scotia. Great strides in the sale of Ford trucks are being made there, and the enclosed cars also are said to be in demand in that territory. About 40 per cent of the business during the past year was enclosed jobs.

T. W. Warner Resigns as G. M. C. Executive

Will Join Durant as Vice President—Zimmerschied Takes Over Duties

NEW YORK, June 13—Thomas W. Warner has resigned as vice-president and general manager of the Muncie Products Co. and the Toledo Chevrolet Motor Co., divisions of the General Motors Corp., to become vice-president of Durant Motors, Inc. His impending retirement from the General Motors organization and association with Durant was forecast in AUTOMOTIVE INDUSTRIES, May 26.

The T. W. Warner Co. and the Warner Corp. at Muncie, Ind., of which Warner is now president, will be kept independent units but will be associated with Durant Motors in the manufacture of transmissions, steering gears and other parts for the new cars. Warner will retain his residence in Toledo and his stock holdings in General Motors, with which his relations are entirely friendly. In joining forces with Durant, he is renewing an intimate association which has continued for years.

K. W. Zimmerschied, who is at the head of the entire Chevrolet organization, will succeed Warner as president of the Toledo Chevrolet company. The retirement of Warner from General Motors will involve no actual change in management, as Warner has merely been the nominal head of the two companies.

Warner is one of the pioneers of the automobile industry. In 1901 he had a gear factory at Muncie, Ind., which was sold in 1909 when he came to Toledo and started the Warner Manufacturing Co. In 1916 this was merged with the Toledo Chevrolet company, a division of the General Motors Corp., manufacturing transmissions for Chevrolet cars. He organized the Warner Corp. about two years ago. He is rated as a millionaire and his active re-entry into the manufacturing field will add much strength to the Durant organization.

G. M. C. Announces Resignation

NEW YORK, June 14—General Motors Corp. has issued the following statement in regard to the resignation of T. W. Warner:

"The General Motors Corp. announces that K. W. Zimmerschied, president and general manager of the Chevrolet Motor Co., has accepted the resignation of T. W. Warner as president of the Toledo-Chevrolet Motor Co. of Toledo, a subsidiary manufacturing transmissions.

"The corporation also announces that Mr. Warner's resignation has been accepted as president and general manager of the Muncie Products Corp. of Muncie, Ind., one of the units of the Inter-Company Parts Division of General Motors Corp.

"Mr. Warner was not an officer nor a director of the General Motors Corp."

G. M. C. NOW PRODUCING 6000 CARS A WEEK

NEW YORK, June 14—Passenger car production of the General Motors Corp., including all lines, is now running at approximately double the rate of five or six weeks ago when it was around 3000 cars a week. Figuring on a basis of 6000 a week, yearly production would be around 300,000, or 75 per cent of production during the feverish period which followed the armistice.

Orders are running ahead of production at this time and in some of the lines, especially Chevrolet and Buick, there are enough on hand now to make necessary a continuance of factory operations at the present rate for at least a month longer.

Mack Truck Sales Cut Inventories $3,000,000

NEW YORK, June 13—President A. J. Brosseau of the International Motor Truck Corp. has informed the directors "that only an utter collapse in general business in the second half of 1921 will be likely to change the apparent gradual gain in the volume of sales, production and profits to which the company may look forward." Current business is running at a rate equal to 85 per cent of the 1920 figures when gross sales amounted to $34,000,000.

Highly gratifying progress has been made in reducing inventories and in the first four months of 1921 there was an actual reduction of $2,000,000. By June 30 the net reduction will amount to more than $3,000,000. No commitments have been made for incoming raw materials beyond those sufficient to meet current manufacturing requirements. It is expected that by July 1 the finished truck inventory will be down to a normal total based on the present volume of business. This means that manufacturing operations at the three plants will have to be increased soon after July 1 to a rate approximating sales. In order to bring down truck inventories, operations since January have been at a smaller rate than monthly deliveries of trucks.

International Motor Truck continues in the strongest financial condition. It has no bank loans whatever and its cash balance approximates $4,000,000. The company came through March without any losses in net profits and there was a slight margin above depreciation, taxes and all other charges. Business now is running at approximately double the 7 per cent dividend requirements.

DEVELOP NEW TYPE AIR WING

NEW YORK, June 13—A new type of airplane wing which materially increases the limiting flying speeds and carrying capacities of aircraft, has been developed by the Dayton-Wright Co., according to General Manager G. M. Williams.

Germain Quits Olds to Join Ver Linden

Lansing Division of Durant Motors Under Way—Other Officials Make Changes

DETROIT, June 14—L. R. Germain will retire as vice-president of the Olds Motor Works to join Edward Ver Linden in the development of the Lansing plant of Durant Motors. Germain, who is a native of Michigan, grew up in the Olds plant, starting as office clerk 12 years ago. He appeared peculiarly adapted to handling financial problems and rose steadily until he was made comptroller about a year ago and was promoted to the vice-presidency.

Concrete is being poured for the Lansing division of Durant Motors headed by Ver Linden. The first automobile produced by this division will be shown about Sept. 1. Contractors have promised to have the building completed Nov. 1, Ver Linden said, and work in every department of the plant will be under way by Jan 1. Announcement is made of the naming of L. D. Maxson, former purchasing agent for Olds Motor Works, as director of purchases for the Ver Linden division.

Another acquisition by the Durant interests is B. H. Anibal, chief engineer of the Cadillac Motor Car Co., who has resigned to join his old chief R. H. Collins. Anibal joined the engineering department of the Olds Motor Works 12 years ago and went with Cadillac in 1911. He aided in designing the Cadillac on which electric starting and lighting were introduced. He rose from designer to assistant designing engineer in charge of motor design, assistant chief and chief engineer. During the war he represented the Cadillac engineering department at Washington and also was assistant chief engineer of the aircraft division of General Motors.

D. B. McCoy, who returned recently from London where he was representing the General Motors Export Corp., has joined the Reo Motor Car Co. as advertising manager, succeeding W. K. Towers, who goes to Paige as advertising manager. McCoy has had long experience in the advertising field, first with Oakland, then with Olds and finally in the advertising section of General Motors Export Division.

TO SELL GENERAL TRACTORS

MILWAUKEE, June 13—William B. Roys, 103 Gay Building, Madison, Wis., trustee in bankruptcy of the General Tractors, Inc., which owns the stock of the Monarch Tractor Co., Watertown, Wis., has announced that on June 25 at 10 a.m. the entire assets of the corporation will be offered for sale at public auction, at the general offices of the General company in Paulsboro, N. J. The next meeting of creditors will be held June 28 at the office of Charles F. Lamb, referee in bankruptcy, Madison.

Ford Payment Plan Would Extend Terms

Move to Simplify Accounts, Says Purchasing Agent—Not Seeking Advantage

DETROIT, June 15—Reports that the Ford Motor Co. is demanding an extension of 10 days in the discount period and 60 days net credit with the idea of gaining a financial advantage, brought vigorous denial to-day from Fred H. Diehl, purchasing agent. As a matter of fact, he said, Ford is now paying cash for materials. He declared a printed circular sent out simply fixes a definite payment period on all invoices.

"The Ford Motor Co.'s purchases over a month range from $40,000,000 to $50,000,000," said Diehl, "and various supply sources naturally fix their own payment terms. This means thousands of invoices coming into the Ford offices each month, each with its own discount dates and terms. In an effort to simplify this work we designed definite terms for billing materials to the Ford company, fixing discount dates on the 20th of the following month rather than the 15th, as heretofore. We were prompted by no motive save a desire for one set of terms on which to pay.

"As for the 60-day stipulation, that is designed simply to protect the company in the event it should become pinched, and is a consideration to which an institution as large as this is entitled just as much as the 90-day payment period allowed banking institutions in case of emergency. We are not asking anyone to carry a financial load and are in no sense trying to shift the burden. We never expect to have to avail ourselves of the 60-day clause, but think we are entitled to that much protection should an emergency arise. This is a matter entirely between our supply sources who are glad to co-operate with us."

President John Kelsey of the Kelsey Wheel Co., probably one of the biggest Ford creditors, declared there was no truth in reports that Ford was demanding a credit extension. On the contrary, he said, the company is paying cash and has been for three months.

Officials of the Holley Carbureter Co. said the circular from Ford had been received, but was fully understood and not considered in any sense a demand for credit or discount extension.

Bankers declare Ford is paying cash and expects to continue now that overhead has been cut to a minimum, and quick turnover insures ample capital.

Parts Makers Disturbed by Ford Payment Plan

NEW YORK, June 15—The Ford circular has caused considerable apprehension among the parts makers with whom he deals heavily. There is no complaint regarding conditions as they exist at present, but these manufacturers assert that they could not carry the financial burden which would be involved if they were called upon to grant Ford 60 days' credit without refinancing their business, which would be extremely difficult if not impossible under present conditions. They take the position they already have borne more than their share of the burdens of the industry in the past year and that no more can be expected of them.

Complain of Payment Date

There also is considerable complaint because of Ford's arbitrary extension of the payment date to the 20th prox. Some parts manufacturers regard this as more serious than the 60-day clause, for the reason that they probably will have to submit to the one while they would not consent to the extension of the credit period. It is contended that this action on the part of Ford wil give him a substantial sum in interest each month, which rightfully should belong to the companies which supply him.

Acason Truck Company Brings Out Light Truck

DETROIT, June 11—A truck capable of speeds over 30 m.p.h. and having a load capacity of ¾ ton is announced by the Acason Motor Truck Co. It is equipped with a four cylinder 3¾ x 5 in. Acason block engine with three point suspension, rated at 35 hp. at its normal speed. The engine accessories include a high tension magneto, Schebler carburetor, centrifugal governor and built-up radiator with detachable core. A disk type of clutch is fitted and the transmission is a Fuller affording three forward speeds and one reverse. There are three universal joints in the propeller shaft, the center bearing of which is a self-aligning ball bearing. Both axles are of Timken make, the final drive being by worm. The frame is built up of steel channels having a 4-1/16 x 2½ x 3/16 in. section. Semi-elliptic springs are fitted all around. The steering gear is of the worm and nut type and is provided with an 18 in. handwheel. Fuel is carried in an 18-gal. tank under the seat, which latter is wide enough to accommodate three persons. Wood artillery wheels are standard equipment and are fitted with 34 x 5 in. non-skid cord tires. Control levers are located centrally. Equipped with a Westinghouse starter, electric lights, generator, Willard 80 amp.-hr. battery, Motometer, three oil lamps, mechanical horn, jack and tools, the truck sells for $1,650.

GIANT AND SUPERIOR REDUCE

NEW YORK, June 15—Price reductions have been made by the Giant Truck Corp., Chicago, and the Superior Motor Truck Co., Atlanta.

The Giant 1½ ton model is reduced from $2,425 to $2,250; 2 ton from $3,250 to $3,150, and 3½ ton, $4,500 to $4,150.

Superior models now are, 1 ton, $1,650, reduced from $1,800, and 2 ton, $2,600, reduced from $2,750.

Durant Denies Plot to Assist Newberry

Had Nothing to Do With Keeping Employees from Voting for Ford

WASHINGTON, June 13—Emphatic denial was made here to-day before the Senate Committee on Privileges and Elections by William C. Durant, former head of the General Motors Corp., that his political sympathies had influenced the votes of employees in his Michigan factories during the Ford-Newberry senatorial campaign. He insisted that he had nothing to do with the alleged action on the part of the executives in the Buick plant to keep employees at work when it was ascertained that their sympathies were with Henry Ford in the senatorial race.

Durant was questioned closely by Senator Spencer, Republican, of Missouri, and other members of the Senate Committee, who are conducting an inquiry into the disturbed election. The automobile manufacturer stated that he knew Senator Newberry slightly, having met him at the Lotus Club. He declared that neither Senator Newberry nor Paul King, his campaign manager, had directly solicited his financial support.

In response to a specific question as to whether or not he had taken action to prevent factory employees from voting when a canvas of the Flint plant had shown a preponderance of Ford votes, Durant admitted that he had communicated with the manager of the Flint plant to ascertain as to how the men stood, but did not take any other action.

"Did you hear that they prevented the men in the Buick plant from voting?" the witness was asked, and he replied in the negative.

"You got a response didn't you, that the men were for Ford," he was asked.

Durant answered: "I do not remember that."

The witness stated that he did not know that notices were posted in the Buick plant that the factory would close at 3 o'clock in order to allow men to vote.

WILLYS CREDITORS REACH PLAN

NEW YORK, June 16—Committees representing the creditors of the Willys Corp., which have been working since March on a refinancing plan which would be satisfactory to all the interests involved, have reached a practical agreement and an announcement is expected in the near future.

OPPOSE STANDARD PARTS PLAN

CLEVELAND, June 15—Stockholders of Standard Parts Co. have voted down the plan of reorganization proposed by creditors. Both preferred and common stockholders agreed to hold out for an extension of the receivership until the depression is ended.

Congress to Act on Truck Dumping

Permanent Tariff Protection Likely

Danger Is Seen, However, in Wide Open Condition Pending Legislation

WASHINGTON, June 15—Protests by motor truck manufacturers and dealers against the serious effect upon their business which will follow continued re-importation of American-made vehicles from England and France, is having its effect upon Congress. Representative Fordney, chairman of the Ways and Means Committee of the House, has indicated that when the permanent tariff is framed adequate protection will be given the automotive industry by the insertion of a specific clause in the anti-dumping provisions of the measure.

Leaders in the lower house are disposed to recognize the justice of the contention that this competition in the truck field is unfair and the same is true of Senate leaders such as Senators Smoot and Ball.

The truck industry itself and the organizations connected with it were slow to awaken to the seriousness of the situation, and it is no secret that if Congress had been informed of the actual facts some such clause as is now sought might have been included in the anti-dumping provisions of the temporary tariff which was passed a few weeks ago.

Senator Smoot, who was especially interested in the subject and who is thoroughly alive to the essential nature of the truck industry, was unable to get the data he sought from any source he could recognize as authoritative.

No attempt will be made to bar out of the country these American-made trucks, but it is proposed to enact valuation clauses which will put them on a fairly competitive basis. The chief danger now is that so many of them will be brought into the country before the permanent tariff is enacted that it will be a case of locking the barn door after the horse is stolen.

It is expected, however, that the Ways and Means Committee will report the permanent tariff bill in a few days. Practically all legislation is at a standstill pending solution of the tariff.

Townsend Bill Gets Committee Approval

WASHINGTON, June 13—Favorable report was ordered by the Senate Post Office and Post Roads Committee to-day on the Townsend bill to create a Federal Highway Commission and to establish an interstate system of public roads.

Members of the commission would be appointed by the President with the consent of the Senate and receive salaries of $10,000. The annual appropriation of $100,000,000 to aid the states in building roads would be continued with the specification that the sums allocated to the states must be expended on interstate roads.

Army Truck Disposal Deadlocks Law Makers

WASHINGTON, June 14—Disposal of surplus army trucks and other motor vehicles has proved a stumbling block for the Senate and House conferees now considering the army appropriation bill. Congressman Anthony of Kansas and a few supporters in the House are demanding that the House managers stand pat on the House provision which would compel the Secretary of War to sell to the public 10,000 motor vehicles. The Senate managers, however, are apparently unwilling to recede from the amendments adopted by the Senate which made it optional for the Secretary of War to sell or transfer to the Department of Agriculture and the State Highway Commissions surplus equipment.

As the present fiscal year is rapidly drawing to a close, it is essential that conferees reach an agreement at an early date in order that funds may be available for the maintenance of the army. There has been considerable agitation by the organized State highway commissioners in behalf of the transfer provision. Congressman Anthony has led the fight for the immediate sale of all surplus motor equipment contending that the road builders in the various states cannot absorb such equipment as may be transferred hereafter. The sale of equipment at depots controlled by the Motor Transport Corps provoked some uneasiness among dealers for a time.

G. M. C. CONSIDERS BODY PLAN

NEW YORK, June 15—The General Motors Corp. is considering a plan of manufacturing custom built bodies at the plant of the Dayton-Wright Airplane Co. The plant is not large enough to permit quantity body production but it offers excellent facilities for custom work.

SHERIDAN TRANSFER AUGUST 1

MUNCIE, IND., June 15—Actual transfer of the plant of the Sheridan Motor Car Co. recently purchased from the General Motors Corp. by interests headed by W. C. Durant, will not be made until Aug. 1. General Motors will continue production of the present models until that time.

Slough Agents Buy More Trucks Abroad

Find Ready Market Here in Chicago and New York Territories

NEW YORK, June 15—Business in reconditioned army trucks brought back into this country by the Truck Company of America, is reported by officials of the company to be well up to expectations. Arrangements are being made by I. Edward Roskam, one of the officers, now in Europe, for the purchase and shipment of a considerable number more.

The first of the trucks brought back, numbering about 2000, were principally Pierce-Arrow, Mack, Packard, Peerless, White, Riker, Locomobile, Liberty, F. W. D., Nash and E. M. C. These were bought from the Slough Trading Co., Ltd., of London, and it is presumed that the trucks now being bought will be from the same source.

Parts for the trucks are now being brought in, according to Louis Mansbach, an officer of the company. These will total in value about $100,000, and it is probable, he said, that more would be arranged for on Roskam's present trip.

Sales of the reconditioned trucks are principally in the New York and Chicago districts, Mansbach said, though the distribution is extending to all parts of the country except through the South. A Chicago office has been opened at 1515-19 Wabash Avenue, under the direction of Morris Froelich, also an officer.

Additional storage space has been arranged for in New York by the leasing of the old car barns on Tenth Avenue, giving the company a total of about 250,000 feet of storage space.

Ohio Governor Signs Truck Restriction Bill

COLUMBUS, June 15—The Burke bill, which practically excludes from the use of Ohio highways trucks with a capacity greater than 3½ tons, has been signed by the Governor. Great pressure was exerted by automotive interests to have the measure vetoed, but these attempts were futile. The measure forbids the use of roads in the State by rubber tired vehicles weighing more than 20,000 lb. including their load. Another section of the bill permits additional restrictions by municipalities.

Automotive interests contended that the result of the bill would be that 3½-ton trucks would be overloaded and operated at a speed which would wear out the highways faster than heavier trucks with a normal load.

Tire Sales Steady at Akron Factories

Business with Dealers Overcomes Decreased New Car Specifications—Prices Stabilized

AKRON, June 13—Although automobile manufacturers' original equipment tire specifications have been materially reduced since the first of May owing to the drop in buying of automobiles, dealers' tire sales are holding up encouragingly, according to Akron tire manufacturers. Few more men will be laid off in Akron tire factories, it is stated, and production is expected to continue on an even keel until automobile sales are stimulated, when an increase in manufacturers' business is anticipated.

In a statement issued by L. C. Rockhill, general sales manager of the Goodyear Tire & Rubber Co., gasoline consumption, which is regarded as a good indication of how much automobiles are being used, was 17 per cent greater for the January, February and March period of this year than for the corresponding period of last year. February gasoline consumption was 9 per cent lower than in February last year, but March consumption was 35 per cent higher than in March last year, indicating, tire builders say, an increasing use of automobiles which will cause consumer tire sales to hold up steadily.

The Goodyear company reports that more automobile tires were sold to dealers last week than during the corresponding week of last year, and also that the week's business to dealers was larger than during any one week since last September. "This reflects an increased consumer demand and is probably the result of the fact that there has been no appreciable curtailment in the use of passenger automobiles," states Rockhill.

Other Akron companies also report that dealers' sales are holding up substantially. Firestone continues on a production basis of about 17,000 tires a day and anticipates no further retrenchment, officials say. Goodrich, although making office personnel reductions, salary cuts and reducing vacations to a one week limit, is producing 15,000 tires daily and not contemplating any further production reduction.

Fisher Body Earnings Establish New Record

DETROIT, June 16—The report of the Fisher Body Corp. for the year ended April 30 shows net profits after all expenses, losses, interest charges, depreciation and Canadian income taxes of $4,809,948, establishing a new record. Earnings for the previous year were $4,378,000. Net profits and surplus brought forward aggregated $11,205,000 from which $5,316,000 was appropriated for dividends on the preferred and common stock, all of which is owned by General Motors Corp., and on the stock of the National Plate Glass Co., a subsidiary. Current liabilities were decreased by the reduction of bank loans from approximately $13,000,000 to $5,000,000. Current assets included approximately $5,000,000 in cash and an inventory valued at $18,000,000 with an allowance of $1,645,000 for reductions in market value.

Sales Not Camouflaged, Asserts Hall Official

(*Continued from page* 1347)

the fairness to our dealers, would state that we have their written acceptance to our plan by contract or otherwise.

"This decision was arrived at only after careful discussion and due consideration here. As discussed with Mr. Whittaker, the plan upon which we are working to a sales end with the fleet owners is common with other of the largest manufacturers of motor trucks, as is evidenced by the fact that many of the fleet owners now have in their possession contracts with these manufacturers for the sale of motor trucks to them direct from the factory at varying wholesale prices.

"It has been intimated, too, that one of the local manufacturers has withheld membership to our association owing to the fact that one of the members of the board of directors was in favor of a sales policy not in accordance with his line of thought; although we have reliable information that the local concern is proceeding in their local sales without a dealer and on a factory direct plan and at wholesale prices, not only to fleet owners but to general users.

"This company values the work of the Sales Managers Association very highly, and the writer has likewise enjoyed the association of the board members, but, inasmuch as Mr. Hall and the writer, on behalf of the motors corporation, are averse to anything but frankness to our fellow associates and companies belonging to the association, we feel that, with respect to your objections, the only course to pursue is this one of resignation.

"Kindly acknowledge receipt and acceptance."

RECEIVER ASKED FOR IDEAL

CLEVELAND, June 14—Federal Judge Westenhaver has taken under consideration application for a receiver for the Ideal Tire & Rubber Co. with a factory in this city. The receivership petition was filed by the Philadelphia Rubber Tire Co., which asked for an accounting. The tire company asserts it is solvent, able to pay its debts and has a substantial equity for its stockholders provided the property is properly administered.

PERFECTION RECEIVER ASKED

WILMINGTON, DEL., June 14—A bill asking for the appointment of a receiver for the Perfection Tire & Rubber Co. has been filed in the United States Court here by the Southwark Foundry & Machine Co. of Philadelphia.

Moline Committees Work Out Financing

Believe Company Will Show $10,000,000 Over Liabilities After Inventory Write Off

NEW YORK, June 14—Creditors' committees which took over the financial affairs of the Moline Plow Co. some time ago are bringing to a conclusion plans for refinancing the corporation on a new scale after the inventories have been written down. Even at scaled down values to meet present prices for raw materials, finished product and plant, the company should show at least $30,000,000 of assets compared with approximately $20,000,000 of indebtedness.

The company, which manufactures agricultural implements and the Stephens automobile, is controlled by the Willys-Overland Co., which owns slightly more than 82 per cent of the common stock. The interest of the Stephens family in the plow company was taken over by John N. Willys in 1918. The former owners of the company received in exchange preferred stock in Willys companies in the following proportions; Willys-Overland 55 per cent, Electric Auto-Lite Corp. 30 per cent, Curtiss Airplane & Motor Corp, 15 per cent.

The bank and merchandise creditors are represented by the following committee: Frank O. Wetmore, Ralph Van Vechten, Edmund D. Hulbert, C. E. Mitchell, R. I. Barr, E. A. Potter, Jr., Samuel Vauclain, Alfred L. Aiken, Festus J. Wade, C. T. Jaffray and C. P. Coffin. The serial note holders are represented by a committee composed of Ronald M. Byrnes, Samuel L. Fuller, J. Herndon Smith, Harold Stanley and William W. Hoffman, secretary, 55 Wall Street.

The two committees made the following statement:

"The sudden and unprecedented falling off of sales in the autumn of 1920 left the company with an increased debt of $10,000,000 above normal, which is reflected in the corresponding increase in its inventory. The management of the business was changed in September, 1919. Important savings in overhead expenses and improvement in matters of organization were effected during 1920. The slump in business came too quickly to enable the company to reap the benefits thereof or to protect itself against the consequently swollen inventory. A new inventory is being taken and analysis of the company's financial position being made. Even at scaled down values to meet present prices for raw material, finished product and plant, the company should show at least $30,000,000 of assets, compared with approximately $20,000,000 of indebtedness.

"The two committees will do everything in their power to preserve this old and valuable business and to refinance the company on a basis that will enable it to maintain and continue the business and prestige it has enjoyed in the agricultural implement business."

Mason Tire Clears Last of High Rubber

Production from July 1 Will Be on Market Basis—Financial Position Strong

AKRON, June 13—Officials of the Mason Tire & Rubber Co. announce that before July 1 the company will have exhausted completely its supply of high-priced rubber, and will base all future production upon purchases of crude rubber at an average cost of 16 cents a pound. It is claimed that the Mason company is the first major rubber company in the United States to use up its high-priced rubber at such an early date, many companies both larger and smaller still have huge supplies on hand of crude rubber purchased at peak prices last year, while there also are many companies handicapped by contractual obligations providing for future deliveries of crude rubber contracted for at last year's record prices.

The fact that the Mason company is not under contract for future delivery of crude rubber at the peak price, places the company in an exceptionally strong position financially, officials say, and will permit a materially lowered producing cost commencing about July 1. Mason production now is running at 1500 tires a day and plans are being made to increase to 2000 tires daily before the first of next month. About 90 per cent of the entire Mason production is cord tires as the company discontinued the manufacture of fabric tires larger than 30 x 3½ some time ago.

Mason officials report May sales were in excess of sales for the corresponding month of last year and state that present business indicated that June sales will show an increase of nearly 100 per cent over June of last year. Mason was one of the few companies to make a 20 per cent tire price reduction on May 2.

Quick Assets $3,340,000

The company on May 1 had current quick assets of $3,340,000 and $778,000 in current liabilities including $433,000 of bills payable, $323,000 accounts payable, and $22,000 accrued payroll. The company also has in process the absorption of the Mason Rubber Plantations Co., which has about $700,000 of quick assets. A short time ago the company offered stockholders of the Plantations company, the privilege of converting their stock into stock of the Mason Tire & Rubber Co. The company expects to have sufficient stock converted by July 1 to take over the Plantations assets.

According to figures issued by the Rubber Association of America covering operations for the month of April in the United States, during which month about 200,000 cord tires were sold to dealers by the leading 45 tire manufacturers, Mason sales of cord tires to dealers during the period totaled 16,000, or from 7 to 8 per cent of all cord tires sold during that month. A year ago Mason discontinued the manufacture of ribbed tread and smooth tread tires, with the result that the money tied up in tire inventory now is small as compared with companies manufacturing several different types of tires.

Mason sales last year were $7,100,000 and the company is operating on an anticipated sales basis of over $10,000,000 for 1921.

New Light Piston Alloy Is Placed on Market

TACOMA, WASH., June 7—The Alloys Motor Parts Mfg. Co. are putting on the market a new copper-aluminum alloy known as Tsungani, which is claimed to differ materially in its physical characteristics from previous copper-aluminum alloys. The tensile strength is said to be over 21,000 lb. per sq. in., the Brinell hardness from 80 to 90, and the coefficient of heat expansion 0.000008. This latter figure is very much closer to the heat expansion coefficient of cast iron than that of other aluminum alloys, and in casting pistons from this alloy it is, therefore, possible to make the skirt clearance as low as 0.00055 to 0.00075 in, per inch of diameter, it is stated. This alloy takes a high polish in wearing

This material has been used for piston rings and also for steam engine piston rod packing. It has had considerable service in the West and has been used for air-cooled aviation engines. Pistons as large as 7 in. in diameter have been cast from the material.

Fox Motors to Produce Air-Cooled Car in Fall

PHILADELPHIA, June 13—The factory of the Fox Motor Car Co. which is owned entirely by automobile owners, has been completed. The new air-cooled Fox car is expected to appear on the market in the fall. The plant comprises 100,000 ft. of floor space and is being fitted throughout with the most advanced machinery and equipment.

The 5-pass. touring car, with 132 in. wheel base, will be sold for $3,500.

HYDRAULIC TO BUY PLANT

CLEVELAND, June 13—Negotiations have been virtually completed for the acquisition by the Hydraulic Steel Co. of the common stock of the Detroit Pressed Steel Co., manufacturer of pressed steel parts and the Disteel automobile wheel. Stockholders of the Hydraulic company are expected to ratify the purchase at a meeting June 24 and virtually all the stockholders of the Detroit company have approved the merger.

MOVE SAMSON OPERATIONS

JANESVILLE, WIS., June 13—General Motors Corp. is transferring the major part of the Samson truck operation from the Samson works at Flint, Mich., to the vast tractor and implement works operated by the Samson Tractor Co. at Janesville, Wis. Parts will continue to be made at Flint.

METAL MARKETS

HAVING reached the irreducible minimum of activity, the steel industry now has its ears to the ground in an effort to detect from what quarter is likely to emanate sufficient fresh demand to warrant the hope that a revival of buying is in the offing. In striking contrast with the attitude of many steel makers at the time of last year's recession in the automotive industries the effect of the different price reductions in the passenger car field is being keenly and sympathetically watched, and hopes for a turn for the better in the steel market are predicted to a considerable extent upon improvement in the automotive field. This change of heart is all the more noteworthy as the steel industry has reason to find fault with the character of automotive buying in the last few months, whereas, during the heyday period, when it was disposed to make light of the importance of the demand for automotive construction, the steel industry had things pretty nearly its own way. In the last few months, however, hand-to-mouth buying has become so general that specifications had nothing alluring about them, and frequently tonnages that, had they been placed at one time and with one or two mills would have been a life-saver for the latter, were so scattered that they were of little benefit to any producer. The strain under which mill executives have been of late in an effort to maintain operations on even the reduced scale of which the prevailing untoward conditions permit has brought about in the minds of many a decision that, when the turn for the better does finally set in, concessions will be strictly reserved for those buyers who are disposed to assume sufficient in the way of risks to enable producers to operate with a comfortable backlog of orders. In other words, there are those steel manufacturers who are beginning to recognize more clearly the advantages of steady production on a close margin over spasmodic prosperity at fancy prices. Especially among the smaller producers one encounters these days many who have begun to lose patience with the theory that in the steel industry there is bound to be either a feast or a famine. Perhaps the day when the steel industry will be so stabilized as to eliminate the proverbially seven fat and seven lean years may never come, but it must be decidedly gratifying to automotive consumers to know that the psychology of many producers is undergoing a decided change and that, when the industry emerges from the valley of idleness through which it is passing, it will set the good will of buyers, which alone can keep its stacks belching, above the fleeting benefit of high prices.

Pig Iron.—Prices continue to sag slightly under the weight of utter inactivity. Foundry No. 2 could probably be bought at $22 valley and malleable at $22.50.

Steel.—There is no longer a definable market price for any steel product. Every order (of the very few that are being placed) is a law unto itself. Published quotations no longer have any meaning. Take semi-finished steel as an illustration in point. Sheet bars are quoted at $39, and yet a northern Ohio buyer is reported to have been offered several thousand tons at $35. Generally speaking, producers have become as apathetic as consumers. Report from Youngstown has it that the Ford Motor Co. placed an order for 20,000 automobile sheets with a Valley producer at 4½ cents.

Aluminum.—There is not the slightest reawakening of demand from automotive sources.

FINANCIAL NOTES

Studebaker Corp. has reduced its bank loans so that they now stand under $1,000,000. Bank loans a month ago were close to $4,000,000 and Jan. 1 about $8,500,000. Studebaker today has about $5,500,000 in cash on hand. Earnings for the first six months of 1921 will approximate $7,000,000 after all charges and Federal taxes. This is about 70 per cent of the total profits for 1920, and more than $10 a share on the $60,000,000 common stock after providing for the full year's preferred dividend requirements. This represents earnings of more than $7 a share in less than six months.

E. & W. Co., Milwaukee, manufacturing commercial car attachments for passenger car chassis, trailers, shock absorbers, etc., has increased its authorized capitalization from $150,000 to $225,000 preferred stock, plus 4000 shares of common stock without par value.

H. H. Franklin Mfg. Co. has declared a common stock dividend of 50 cents a share payable July 11. Profits for the first five months of 1921 are estimated at $775,000 after taxes. The factory is at 100 per cent capacity.

Gotfredson-Joyce Corp., Ltd., Walkerville, Ont., truck maker will increase its capital stock from $100,000 to $500,000. The company has been building 2-ton and 3½-ton models and will bring out 1-ton and 5-ton models.

Necedah Mfg. Corp. has been incorporated with a capital stock of $200,000 to succeed the Necedah Mfg. Co., at Necedah, Wis., established about a year ago to manufacture electro-generating units, farm lighting plants, etc.

J. I. Case Plow Works has passed the quarterly dividend of 1¾ per cent on its first preferred stock. Three months ago the company passed the dividend on the second preferred stock.

C. R. Wilson Body Co. directors have authorized payment of the regular quarterly dividend of 1¾ per cent on preferred stock. The payment will be made July 1.

Electric Storage Battery Co., Philadelphia, will pay a quarterly dividend of $3 a share on both common and preferred stocks, payable July 1.

Auburn Automobile Co. has declared a quarterly dividend of 1¾ per cent on preferred and $1 on common, both payable July 1.

Kelly-Springfield Tire Co. will pay a quarterly dividend of $1.50 a share on the 6 per cent preferred stock on July 1.

Moon Motor Car Co. has declared a quarterly dividend of 1¾ per cent on its preferred stock payable July 1.

Fisher Body Ohio Co. paid June 10 the quarterly dividend of $2 a share on its preferred stock.

Motor Wheel Corp. paid a quarterly dividend of 2 per cent on the common stock June 10.

INDUSTRIAL NOTES

Gillette Rubber Co. of Eau Claire, Wis., is now turning out 250 cord tires a day, the largest output of this class of goods it has ever attained. Production also includes 400 fabric casings and 1400 to 1500 tubes.

Clark Turner Piston Co., Los Angeles, has appointed Laystall Motor Engineering Works, Ltd., London, as distributors of De Luxe pistons for Great Britain and Ireland.

New Departure Mfg. Co. has removed its Chicago sales office to the Peoples Gas Building, 122 South Michigan Avenue.

Canton Foundry & Machine Co., Canton, Ohio, has moved its New York office to 45 West Eighteenth Street.

G. M. C. Plans Future Use of St. Louis Factories

ST. LOUIS, June 14—C. S. Mott of Detroit, vice-president of General Motors Corp., in a letter to President W. Frank Carter of the St. Louis Chamber of Commerce, writes that the St. Louis plant of General Motors is not for sale at any price and adds that "we expect to make it one of the most active in our organization." The letter is in reply to a query by the Chamber as to the foundation of current rumors that the corporation was planning to dismantle and eliminate its plant here.

"The new management of the General Motors Corp.," the letter says, "is perfectly satisfied with the St. Louis investment, its geographical location, railroad service and labor market. We feel sure you will be pleased with our plans when the time comes to put them into operation."

FINANCE OBENBERGER WORK

MILWAUKEE, June 13—Permission has been given J. F. Gerdis, as trustee of the John Obenberger Forge Co., Milwaukee bankrupt, to borrow $60,000 from the First Wisconsin National Bank for the purpose of financing current production, resumed recently by authority of the Federal court. The Obenberger company has sizable orders from Packard, Nash, Dodge and other passenger car factories, and reinstatements of other orders which were cancelled about eight to ten months ago, precipitating the financial crisis in January this year. The loan is secured by short-term certificates bearing 7½ per cent interest. The First Wisconsin National Bank is one of the largest creditors and is assisting in the rehabilitation of the concern. The liabilities of the Obenberger company are about $1,250,000 and its assets are in excess of $2,000,000.

ONEIDA SEEKS NEW CREDIT

GREEN BAY, WIS., June 15—Directors of the Oneida Motor Truck Co. have submitted to creditors of the company a new proposition which it is asserted will result in a satisfactory adjustment if it is accepted. The company has found it impossible to carry out the tentative agreement made with creditors in April. The new plan is understood to call for a substantial cash payment to creditors.

CANADIAN FORD DIVIDEND

WINDSOR, ONT., June 10—The Ford Motor Co. of Canada has declared its regular annual dividend of 15 per cent.

BANK CREDITS

Written exclusively for AUTOMOBILE INDUSTRIES *by the Guaranty Trust Co, second largest bank in America.*

NEW YORK, June 16—The local call money market eased in the middle of last week, after having maintained, for the first few days, the firmness which had characterized the previous week. The range for call money was 6 per cent to 7½ per cent, as against 7 per cent to 8 per cent the previous week. After opening firm at 7½ per cent on Monday, the rate on call loans declined, until on Friday a uniform rate of 6 per cent was quoted all day. In the latter part of the week, offerings were more abundant, and, it was said, there was a surplus of loanable funds. "Outside" money was available at 5½ per cent. The favorable report of the Federal Reserve System and the offering of treasury certificates of indebtedness and Government short-term notes seem to have created a favorable impression in money circles in midweek. Time funds, however, were still scarce, and quoted rates were unchanged at 6¾ per cent to 7 per cent for all maturities from 60 days to 6 months. As a result, quotations were nominal and transactions few.

Gold holdings in the United States were, on June 1, the largest in the history of the country. On June 1, the total stock of gold was $3,175,037,198. The previous high record was on May 1, 1917, when we held $3,121,887,443. Our gold holdings increased $85,357,416 in the month of May, and $390,202,771 during the first five months of the present year. These holdings have further increased since the first of the month.

The Government crop report issued on June 8 estimates the year's harvest of wheat, oats, rye and barley at 88,000,000 bushels under last year's harvest. The estimate for these combined crops is 2,496,000,000. The estimated wheat crop of 829,000,000 bushels is comprised of 578,000,000 bushels of winter wheat, and 251,000,000 bushels of spring wheat, and allows for an exportable surplus of about 200,000,000 bushels. While there were some crop losses in May as a result of drought and freezing, indications now point to a more favorable wheat crop. Since the Government report was issued, rains and cool weather have contributed toward the filling and maturing of the crop. Present indications also point to one of the largest oat crops in our history, should present conditions and acreage maintain until harvest time.

KELLY CLEARS TRUCK SURPLUS

SPRINGFIELD, OHIO, June 13—Indications are that the plant of the Kelly-Springfield Motor Truck Co. will be forging ahead in good shape within the next sixty days, according to officials at the plant. Eastern warehouses are being freed of the surplus trucks and general demands are increasing. At present the big works is operating with about 30 per cent of its normal force.

MEN OF THE INDUSTRY

E. C. Tibbetts, who has resigned as advertising manager of the B. F. Goodrich Co. after having been with Goodrich for 24 years, has become central western manager for the William H. Rankin Co. He will have headquarters in Akron, and in his new capacity will have direct charge of the Goodrich advertising account with the Rankin agency. E. P. Rowen, another veteran Goodrich employee who has resigned as manager of Diamond tire sales, has been succeeded by E. H. Fitch, with Ralph McPeake named assistant to Fitch. L. A. McQueen, formerly in Goodrich sales promotion work, has been made assistant advertising manager.

Arthur R. Heiskell, who has been connected with Nordyke & Marmon Co. as treasurer for a number of years, and H. G. Shafer, who has been secretary, have been named vice-presidents of the company. H. L. Purdy, formerly assistant treasurer, will succeed Heiskell, and H. H. Rice, formerly sales manager, will take Shafer's place. H. H. Brooks, assistant sales manager, has been promoted to take the place made vacant by Rice and A. J. Rogers, publicity manager for the company, has been promoted to assistant sales manager.

H. M. Rugg, for two years director of the Department of Technical Instruction of the United Y. M. C. A. Schools, has become director of Educational Extension of the Michigan State Automobile School, Inc., Detroit. His new duties involve the sales and promotion work for the school as well as assistance in technical supervision. Rugg was active in training work with the army during the war.

Alfred Reeves, general manager of the National Automobile Chamber of Commerce, has been elected president of the Trade Organization Secretaries of New York, which consists of the executive officers of more than 80 trade organizations. The association holds monthly meetings to discuss problems which have to be met by organizations of manufacturers, wholesalers and retailers.

J. H. Newmark, for 11 years with General Motors, recently as advertising manager of the Chevrolet division, has been promoted to assistant manager of sales and will come to Detroit when the Chevrolet organization moves to its headquarters in General Motors building July 1.

Wilis Johnson has been appointed vice-chairman of the appropriations committee of General Motors Corp. His duties will be to handle all matters pertaining to requests for appropriations for capital expenditures from the divisions and subsidiaries of the corporation.

William R. Petze, sales manager of branches for the Splitdorf Electrical Co., has resigned and joined the Sterno Corp. as general sales manager of its automotive accessories division. His headquarters will be at the general offices of the Sterno Corp., New York.

F. W. Warner, former president of the Oakland Motor Car Co., who has remained a director and vice-president of the General Motors Corp. since he relinquished active control of Oakland's affairs, is expected to join the organization now being built up by W. C. Durant later in the year.

S. H. Cunningham, New York branch manager for the Goodyear Tire & Rubber Co., has resigned. Cunningham has moved to Akron, where he announces he will engage in private business in the future. He had been with Goodyear for several years.

William E. Corey, chairman of the board of the Midvale Steel & Ordnance, has been elected a director and member of the executive committee of the International Motor Truck Co. in place of Ambrose Moonell, deceased.

G. C. Jefferson, formerly in the sales promotion department of Oakland Motor Car Co. and later with the W. N. Albee Co., Detroit, has joined the advertising department of Briscoe Motors Corp, Jackson, Mich.

W. G. Bell has resigned as president of the Cleveland Tractor Co. of Canada to become director of sales of Gray-Dort Motors, Ltd., of Chatham. Johnson R. McGee has been named Gray-Dort sales manager.

John D. Hess, Jr., has been appointed manager of pneumatic tire sales for the Firestone Tire & Rubber Co. He has been with Firestone for nine years, latterly being assistant western sales manager.

Dexter C. Hathaway has been appointed assistant sales manager of the McGraw Tire & Rubber Co. He has been connected with the McGraw Cleveland branch for the past year.

Ted Snider, formerly manager of the Cincinnati district of the wheel division of General Motors, is now general factory representative of the Gary Motor Truck Co., Gary, Ind.

C. E. Gordon has resigned as sales representative with the Timken Detroit Axle Co. and has been made general sales manager of the Alena Steam Products Co. of Indianapolis.

C. J. Reilly, for several years connected with Firestone and Akron, as sales representative, has been made sales manager of the Simplex Auto Lock Co., Detroit.

C. E. Pumphrey, formerly sales manager for McGraw Tire & Rubber Co., has been appointed sales manager for the Corona Cord Tire Co., Butler, Pa.

Robert S. Gans has been elected a vice-president of the Raymond Engineering Corp. He will continue in charge of sales and the development of new products.

Oshkosh Tractor Formed to Take Over La Crosse

OSHKOSH, WIS., June 13—As the preliminary step toward the transfer of the works and offices of the LaCrosse Tractor Co., manufacturer of the Happy Farmer tractor, from LaCrosse, Wis., to Oshkosh, Wis., a new corporation styled the Oshkosh Tractor Co. has been incorporated under the laws of Wisconsin. The capital stock consists of $1,500,000 preferred stock and 15,000 shares of common stock without par value. The articles are signed by Harvey P. Rhyner, Milo J. Gilbert, Bart W. Heiss, Edgar Melzer and E. J. Dempsey, attorney, all of Oshkosh.

Oshkosh capital is becoming heavily interested in the new corporation and the present owners of the LaCrosse company will absorb the remainder of the capital. Plans are being prepared for a new factory building. A. D. Paine, who has been Wisconsin distributer of the Happy Farmer tractor for several years, is active in the reorganization.

At LaCrosse the company operates two works, widely separated, with no immediate prospect of a union of the operation. To facilitate production and operate efficiently, it was decided to accept the offer of Oshkosh capital to relocate in that city, provision being made locally for the erection of suitable buildings.

It is expected that the actual transfer of the equipment and stock of the LaCrosse company to the new Oshkosh works will be possible about August 15 or Sept. 1.

Fort Wayne Tire Plant to Be Offered for Sale

FORT WAYNE, IND., June 13—Property of the defunct Fort Wayne Tire & Rubber Mfg. Co. is valued at $273,000 while liabilities approximate $200,000, according to the inventory and appraisal filed with Harry C. Sheridan, referee in bankruptcy, by David S. Vesey, trustee. The date for the sale of the company property has not been set.

The plant is not being operated at the present time. Such manufactured stock as there is on hand has been offered by Vesey at retail sale at prices far below the regular prices of the goods. A plan is now being worked out which, it is hoped, will enable the old stockholders to reacquire the property and start operations. The investigations into the company's affairs conducted by the trustee in bankruptcy lead him to believe that with efficient management the property can be successfully operated even under present business conditions.

DODGE-RACINE TO MOVE PLANT

SHEBOYGAN, WIS., June 13—The Racine Engineering Co., Racine, Wis., manufacturer of the Dodge-Racine tractor-truck, has definitely decided to relocate in Sheboygan, Wis. It is being reincorporated as the Dodge-Sheboygan Co., with a capital stock of $200,000. Temporary quarters are being provided until the construction and equipment of a new tractor plant in Sheboygan can be accomplished. The Dodge design is new and novel, as it embraces a motor truck and farm tractor in one machine, making it adapted for trucking, hauling, cultivating, etc. The machine will be marketed under the trade name of Dodge Universal Truc-Trac.

CONGRESSMAN GOOD RESIGNS

WASHINGTON, June 13—Representative James W. Good of Cedar Rapids, Iowa, chairman of the Appropriations Committee of the House, who has been one of the most insistent members of Congress in urging additional taxes upon motor vehicles, has resigned to take up the practice of law in Chicago. He announces that he cannot afford to continue longer in the public service at the low salary he receives.

Calendar

SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Ice ander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

RACES

June 18—Uniontown, Pa., Speedway Events.

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Equipment Association Plans Increased Sales

CHICAGO, June 13 — A half day's session at the summer convention of the Automotive Equipment Association at Mackinac Island next month will be devoted to discussion of means of developing the channels for retail distribution. Jobber and manufacturer members of the association, at this session, will make an intensive study of resale merchandising with a view to bringing influence to bear to broaden the outlets for the products of the industry.

The first two days of the convention, July 4 and 5, will be given over to meetings of the directors, standing committees and state vice-presidents. Routine work will be taken up at the morning meeting July 6 and in the afternoon there will be meetings of the manufacturers' and jobbers' divisions, presided over respectively by President Robert A. Stranahan and Commissioner William M. Webster. The sales meeting will be held July 7 and on Friday, July 8, the convention will be brought to a close with the morning session.

Members of the association from all parts of the United States and Canada are making arrangements to attend the meeting, a large number planning to go by boat from Buffalo or Chicago.

N. A. C. C. ISSUES TAX BOOKLET

NEW YORK, June 13—The National Automobile Chamber of Commerce has issued a booklet on national taxes showing motorists what they pay in special taxes and outlining the program proposed by the industry in opposition to excise or "stigma taxes." The booklet shows that motorists pay annually $267,000,000 in discriminatory excise taxes.

WISCONSIN BOND RATE HIGHER

MILWAUKEE, June 14—The Wisconsin Legislature has passed and the Governor signed a 6 per cent interest rate provision for county highway bonds. During 1919 many counties bonded themselves for large amounts for the construction of highways under the Wisconsin and Federal aid provisions. The State law at that time fixed interest on the bonds at 5 per cent, and provided the bonds must not be sold for less than par. These limitations during the past two years made it impossible to sell the bonds, as against other securities on which interest returns grew in the tight money market. The new law not only permits future issues of 6 per cent bonds, but enables county boards to issue bonds already voted for issuance, at 6 per cent.

Duesenberg Quits Racing to Build Stock Cars

INDIANAPOLIS, June 14 — L. M. Rankin, vice-president and general manager of the Duesenberg Automobile Co. here, this week said the corporation was leaving the racing game and after the Grand Prix and the Uniontown race its energies would be devoted entirely to the production of stock machines. Any race entries hereafter containing Duesenberg engines will be private mounts.

Duesenberg declares that the company will stick to the eight-in-a-row engine in stock cars. The Deusenberg models will be priced from $5,000 to $8,000 and will include a complete line of open and enclosed models. The body designs are now being perfected.

The company is headed by B. A. Worthington, who is president of the Cincinnati, Indianapolis & Western Railroad and chairman of the industries committee of the Indianapolis Chamber of Commerce. L. M. Rankin, vice-president and general manager, is an executive and sales manager of long experience. F. A. Reilly, secretary-treasurer, is a New York attorney.

WALLACE TO ADDRESS N. I. V. A.

CHICAGO, June 14—An address by Henry C. Wallace, secretary of the Department of Agriculture, will be the feature of the twenty-eighth convention of the National Implement Vehicle Association which will be held in this city Oct. 12-14. It is expected that other speakers of national repute will be secured. To assure accommodations for delegates who desire to be in Chicago the day preceding the opening session, arrangements have been made with the Congress Hotel, convention headquarters, for reservations for the four days.

Fiat Defeats Mercedes in Targa Florio Race

PALERMO, SICILY, May 31 (*By Mail*)—Fiat defeated Mercedes in the first European automobile race open to late enemy countries. The occasion was the twelfth annual Targa Florio 268-mile race around a mountainous course on the island of Sicily. Count Masetti, an amateur, covered this distance on a 300 cu. in. racing Fiat in 7 hr. 21 min, 05 sec., or at an average of 36½ miles, thus winning first prize and breaking all previous records.

A week before the closing of entries the German Mercedes Co. announced that it would take advantage of the open rules to enter this race, and a team was sent comprising three 6-cylinder cars of 105 by 140 mm. bore and stroke, to be driven by Lautenschlanger, twice winner of the French Grand Prix; Seiler, and Gros. No expense was spared to secure success in the race, and in view of the high quality of the cars and the reputation of the drivers, it appeared doubtful if the Italians, who were about thirty strong, could win the trophy.

This race resolved itself into a duel between Seiler, the German driver of the Mercedes, and Masetti on the Indianapolis type Fiat. On the first of the four laps the German led by 19 seconds. At half distance Masetti had worked his Fiat into the leading position with a margin of 2 min. 29 sec. On the third lap the German closed up until the Italian had a lead of less than 1 min., but the Mercedes weakened toward the end, and the Fiat finished with an advantage of 6 min. 11 sec. Compared with track performances, the average looks low, but the race was one of the hardest ever run in Europe, for more than 6000 sharp turns had to be negotiated in the 268 miles, and the only level portion of the course was very rough.

The following is the result of the race:

Masetti, Fiat	(300 cu. in.)	7.21.05
Seiler, Mercedes	(460 cu. in.)	7.27.16
Sivocci, Alfa-Romeo	(274 cu. in.)	7.31.43
Ferrari, Alfa-Romeo	(274 cu. in.)	7.33.45
Forestri, Itala	(183 in.)	7.34.37
Morlandi, Itala	(183 cu. in.)	7.39.34
Minola, Fiat	(183 cu. in.)	7.47.46
Ceirano, Ceirano	(183 cu. in.)	7.59.12
Bergese, Fiat	(120 cu. in.)	8.06.34
Arnone, Ceirano	(183 cu. in.)	8.11.11
Febo, Fiat	(120 cu. in.)	8.36.59

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, JUNE 23, 1921 NO. 25

Team Work Needed in Bucking the Sales Resistance Line

Now that the price question is in eclipse for the time being, there are other important sales questions. Some of those that must be met by the industry are here set forth. These do not call for so much individual action, as action by the industry.

By Clyde Jennings

NOW is the time for all good men to rally to support of the industry. How well most of us remember writing the above line (with a slight difference) when we first attempted to use the typewriter.

And using the typewriter is about like David Harum's low bridge story. Practically every business executive smiles at references to his one-finger speed.

But let us begin on the topic actually under discussion.

The automotive industry has pretty well got the price troubles out of its system. It is now ready to sell the motor cars, if the public can be persuaded to buy, and the public can be persuaded if it is properly approached. There are, however, a number of serious questions now entering into the sale of motor cars that have not been serious in the past. It is in the solution of these problems that the assistance of "all good men" is needed. The questions that will be set forth are not questions for the Maxwell, the Dodge, the Buick, the Cadillac or the Pierce-Arrow to answer. They are questions for the industry to answer.

We all know what the stage setting has been in the past. It has been like this:

Every man, woman and child in the country has had the desire to own a motor car. It was only a question of the prospect getting money enough to buy one or the seller making terms long enough to permit the prospect seeing a chance to get it paid for eventually.

When either horn of this dilemma was met, the signature went on the dotted line and another car was started on its way to the used-car boneyard.

Times change and selling conditions and public opinion change with time. To-day the salesman hears many objections besides that of "I haven't the money." Any salesman to-day will tell you that:

It is easy to find a man who says:

I figure that I can buy a $1,000 car and pay a reasonable upkeep, but I cannot afford to pay $35 or more a month for garage space.

I can probably afford a car and a reasonable upkeep, but traffic regulations in this town are so bad there is no pleasure in keeping a car.

I can afford a car as things are now, but they are talking about raising the license fees and putting more taxes on the cars, and I am afraid.

I am waiting for the car that will go twice as far on the fuel.

I don't want to buy a car just to have it stolen.

My neighbor has a car. He is a safe driver, but the insurance people are making him pay as much insurance as any speed demon, and it's too much.

There are not enough good roads. Where I want to drive, it is a procession, not pleasure driving.

There is too much danger of killing people with a car; too much danger of being sent to jail.

My brother bought a car because he read how economical it was in operation, how silent and many other things. It won't do those things.

I am having troubles enough these days. Why should I buy a car and fight all of the time with repair men. You folks do not take care of your cars.

If we reduce these points a bit further, we get these lines of sales resistance:

Shelter in cities.
Traffic conditions.
Taxes.
Gasoline scarcity talk.
Car thefts.
Insurance abuses.
Highways.
Accident cry.
Foolish publicity.
Poor service.

These are actual lines of resistance in selling cars to-day. The public, according to reports from the men who actually sell the cars, is not much alarmed by the average life of the car and many other things that will, in time, come up for solution.

The public, it appears, is pretty well sold on the utility of the car and its internal combustion engine kindred, and the public has a great desire to own cars. But especially since last July 1, last year, a good many individual sections of the great public have been giving more and more thought to financial problems, as pertains to the individual, and the era of reckless expenditure has ended. It took the industry generally a long time to fully appreciate the individual's increased appreciation of the importance of his own pocketbook, but the recent price adjustments and the change appearing in the subject matter of the advertising indicate that an understanding of the present situation has been finally lodged in the sales mind of the industry.

Shelter

This is a question that can be solved only by proper encouragement to capital. It is very akin to the housing of families—only of less vital importance to the human race and the nation. It is important chiefly to those who have automotive vehicles for sale. The prospective buyer will not make any great exertions on his own behalf. It is the belief of many students of the situation that a proper canvass would show to capital that there is a productive field. Also that a new type of garage is needed. This should be a garage where the flat-resident owner can drive his car and lock it up. City car owners are tired of having tools and other articles left in the cars stolen. The practice of losing these articles and of being ordered to vacate garage space because they buy gas and oil elsewhere is an annoyance that may counterbalance the sense of satisfaction of owning a car.

Traffic

Traffic regulations are far from satisfactory. Generally speaking, in the small city they are too loose and in the large city they are too severe. Someone besides the police sergeant should study traffic needs and regulations. In each city the persons most concerned with the proper use of automotive vehicles should interest themselves to see that the existing regulations are properly enforced.

There was a time when this matter was entrusted entirely to the motor car owner. All are familiar with the present situation. Surely this question is of sufficient importance as a sales resistant to warrant attention. An automotive student recently visited a Massachusetts city. He said sales were at a standstill there because the downtown streets were so full of cars people were disgusted. He did not see the solution, but after some discussion he admitted that a proper enforcement of reasonable parking restrictions would do much to clear the streets. In larger cities parking space where car owners can pay for the service they want is required.

Taxes

This question has been much discussed and much effective work is being done by the Motor Conference Committee and by the N. A. C. C. Legislative Committee. It is only necessary here to say that this work is much too important to be neglected. A foundation of continuing work has been laid and it must be continued.

Gasoline Scarcity Talk

Once we all thought that when the price of gasoline dropped it would end the scarcity talk. But apparently it does not. So many scientists who view time only by geological ages have been writing of the end of the gasoline supply that they have made a pessimist of the ordinary man. There must be some reasonable counter-argument. Some persons who have carelessly read these articles are refusing to buy cars because they believe the supply of gasoline will run out before the car wears out.

There is another view of the gasoline situation that may be worthy of note. That is the small size of the gallons that some retailing machines turn out. This is especially a question where the motor vehicle owner is forced to rent shelter in a public garage, the kind that shelter most of the vehicles owned by apartment house dwellers and even in dwelling houses where no provision was made for a private garage. These short gallons also have a considerable effect on mileage-per-gallon records that owners pass to each other by word of mouth.

Car Thefts

Despite Federal laws and exposures of reward scandals in several of the larger cities, this evil flourishes. It is a serious sales resistant. In some states and cities an effort is being made to solve the problem. The motor vehicle is the most costly article that lends itself readily to theft. The best progress that has been made toward stopping thefts has been made under the encouragement of dealer associations. These efforts have demonstrated that when police and prosecuting officials are properly encouraged and assured of proper criticism in case of failure, and proper support in case of effort and proper credit in case of success that, they can materially change the situation.

Highways

This is not a new subject at all and the work is well under way. Now that the effort is being directed toward definite and well-defined ends, much progress is likely to be made. One important movement in the last year was the decision within the industry to stop the support of all wildcat schemes, which existed primarily to provide some nimble witted man with a job. The unity and earnestness of the industry in this cause is commendable.

Insurance

Ask any car owner about his insurance and you will get a rise out of him. Recently some steps have been taken by the insurance companies to right some of the most

flagrant wrongs, but much injustice still exists. The careful driver to-day feels that he is penalized because of the reckless person over whom he has not the slightest control. He feels that his good record amounts to nothing. Insurance folk are apt to think they have had small co-operation from car manufacturers. As a matter of fact, the insurance folk are having troubles of their own and they are ready to listen to constructive criticism. It is strange, but true, that there are no fundamental statistics on automobile accidents.

Accident Cry

While this article was being written a man who is financially interested in the industry came into the office and incidentally mentioned the "fear of injuring some one" as a great deterrent in his own case as to buying a car. He said that he heard many persons speak of this from day to day. Recent insurance company curves show that the 1921 automobile accident percentage per 1000 population is running higher than the 1920 curve.

Some recent statistics have indicated that the middle-sized cities are the worst offenders in this line. The usual idea is that it is the largest cities, but this idea is probably due merely to the fact that the numbers of those injured run higher, without a proper sense of proportion to population. There is opportunity here for research into the cause, time and place of accidents and then a broad educational campaign. This problem is closely linked with the general safety problems and even more closely linked with the regulation of traffic. At present the entire burden is passed to the driver. Much of it, doubtless, should go to the pedestrian. But accurate figures are lacking.

Foolish Publicity

Too much is promised for the car in hastily written publicity notices that have no object other than getting people to read them. They make all sorts of promises as to silent performance, mileage of gasoline and tires and many other promises that cannot be kept.

Also the public is getting a very queer impression of the sagacity of leaders in this industry because of some of the quotations attributed to them in the public press. Some executives might learn a good deal if they would keep posted as to their published opinions.

Poor Service

It looks a good deal like butting your head against a stone wall to talk about better service being forced by the manufacturers. However, the success of some manufacturers who have begun to take this question seriously is decidedly encouraging. Undoubtedly the Factory Service Managers of the N. A. C. C. are doing a great work. They should be encouraged. As an offset to this, the manager of a large truck factory recently said that he made 10 per cent on his trucks and 25 per cent on his parts. Apparently the only obligation of this manufacturer toward his customers is to use him as a means of making money.

Among the persons who write to Automotive Industries on topics uppermost in their minds is George M. Brown, a pioneer dealer, who wrote recently:

"Several things happened to-day which brought to my mind rather forcibly the general character of the automotive industry, with which I have been associated for many years.

"That there is a strong tendency to a slump in the business is hardly to be denied, and it may not be entirely the price of cars. The upkeep to-day is a very serious factor. The high cost of repairs and the take it or leave it policy, very prevalent now, is not conducive to encourage even the purchase of a low-priced car.

"Years ago, when I was in the automobile business, my great aim was to satisfy my customers, even if the customer was somewhat unreasonable. A week or so ago my car needed new cylinder gaskets. These, on being applied, immediately blew out. On returning to the service station of the car I made a mild kick and was met with the retort, 'We don't make them, we only sell them.'

"I really think that many people are getting tired of a continual holdup because they happen to own a car. It may be necessary for some one to emulate the attitude of Admiral Simms and George M. Cohan and say a few words straight from the shoulder regarding some of the abuses outside the primary factory industry."

There is only one thing about this letter that is not satisfactory; that is that Brown does not give us credit for having hammered along these lines.

There is one thing very certain. With an article to sell like the motor car, a sales campaign that does not take service into consideration will never be a success.

Now this is not in any sense a "blue Monday" effort, nor is it designed to give expression to a grouch. But there is more to selling than naming a price and taking the article bought off of the shelf. No mercantile establishment ever laid the foundation for a fortune by merely wrapping up the merchandise. It is a fact, nevertheless, that a lot of manufacturing companies are started without giving any study to the selling problem. A lot of them start without even looking over the field with a view of possible absorption of the product.

There will be nothing new in this article to good salesmen, but whether the subject on any part of it is new, it is time that there was unity in the effort to meet the condition.

Census Bureau's Summary Concerning Aircraft Manufacture

A PRELIMINARY statement of the general results of the 1920 census of manufactures with reference to aircraft has been issued by the Bureau of the Census, Department of Commerce, furnishing a detailed statement of the quantities and values of the different types of aircraft manufactured during the year 1919, prepared under the direction of Eugene F. Hartley.

Reports were received from 31 establishments engaged in the industry during 1919 showing products for the year valued at $14,372,643, as compared with 16 establishments in 1914 with products valued at $789,872. Of the 31 establishments reporting for the year 1919, 10 were located in New York; 4 in Ohio; 2 each in California, Massachusetts, and Missouri; and 1 each in Connecticut, Indiana, Illinois, Louisiana, Maryland, Nebraska, New Jersey, Pennsylvania, Rhode Island, Washington and West Virginia.

The following is a summary of statistics of the industry for 1919, the "All other products" reported consisting chiefly of airplane parts, engines, and repair work.

Number of establishments	31
Total value of products	$14,372,643
Airplanes:	
Number	432
Value	$3,466,452
Seaplanes:	
Number	230
Value	$4,580,016
Value of work done during year on airplanes and seaplanes not completed	$1,658,670
All other products, including parts and repair work	$4,667,505

Nearly 65 Miles on One Gallon of Benzol

New record is established in French Grand Prix fuel consumption test by Gregoire, Citroen and other small cars, as well as by some larger cars. Nearly all makes entered in 183 cu. in. class and smaller make over 30 m.p.g. Only stock cars were admitted. One Ford makes 38.81 m.p.g.

By W. F. Bradley

NEARLY 65 miles on one gallon of benzol was the record set up by Jean Porporato, driving a two-seater Gregoire light car with a four-cylinder 2.4 x 3.5 in. engine, in the French fuel consumption Grand Prix at Le Mans.

This was not the only record broken, for right along the line, from the small two-seaters of 61 cu. in. piston displacement to the full-sized seven-passenger touring cars, extraordinary figures were shown and old records were broken. There were five classes, of 1100, 1400, 2000, 3000 and 4500 cu. cm. displacement, in which the best performances were Porporato on Gregoire, 64.62 m.p.g.; Milcent, four-passenger open Citroen, 62.03 m.p.g.; Bocchi, four-passenger open De Dion Bouton, 49.09 m.p.g.; Korner, four-passenger open Ford, 38.81 m.p.g.; Artault, four-passenger open Voisin, 36.59 m.p.g.

Each of the forty competitors was given a certain amount of fuel, according to piston displacement, seating capacity, weight and type of body, and all were sent away on a carefully guarded course about 4½ miles round, over which they had to run until the fuel supply was exhausted. The winner could be considered either as the one traveling the greatest distance, or the one showing the highest mileage per gallon. The results were different, according to which method of classification was employed. Thus, Milcent's Citroen went the greatest distance before stopping with an empty tank, but its mileage per gallon was less than that of Porporato's Gregoire. The Ford was first in its class on the basis of miles per gallon, but dropped down to seventh place on the basis of actual distance covered. In the big car class, too, Artault, on the open, sleeve-valve Voisin, was beaten by his teammate Cabaillot with a seven-passenger Voisin Sedan, on the basis of total miles run, for he put up a record of 79.39 compared with 76.84.

Competitors could select their own fuel, and in nearly all cases benzol was preferred to gasoline. Mixtures of gasoline and benzol were not used, and the few who did use gasoline preferred heavy grade to light fuel. Lacharnay equipped the Gregoire car which showed the highest mileage per gallon; Solex furnished the carbureter for the winners in the 1400, the 2000 and the 3000 cc. classes, while the Voisins in the 4500 cc. category had Zenith carbureters modified according to the ideas of the Voisin engineers.

The competition called forth the best work of French engineers and carbureter experts, and although the results obtained are not within the reach of the average automobile owner, they are valuable as an indication of directions in which economies can be made, and they are significant by reason of the improvement over the trials of a year ago. Only stock cars were admitted, but changes could be made when they had in view increased fuel efficiency. For instance, special camshafts and pistons could be used, the timing could be changed, compression increased, ignition and carbureter could be special, there could be electric heating for the carbureter and oil, if desired. It was forbidden, however, to change the type of engine, and if the standard product was an L-head engine it was forbidden to use an overhead valve type.

Speed was not sacrificed to fuel economy, except in a few cases. The big cars ran at 30 to 35 m.p.h., and in

Cars competing in the French fuel consumption Grand Prix

Filling the fuel tank of one of the cars (Voisin) prior to running in the French fuel consumption Grand Prix

the afternoon of the same day, without any adjustments in the meantime, many of them put up speeds of 60 m.p.h. for a distance of about 65 miles.

One of the features of the competition was the tendency to make use of crankcase induction. This was allowed under the rules, and interesting work was done by the Zenith engineers and by Cozette, a French carbureter expert. On a four-cylinder De Dion Bouton sedan, with four passengers, it was possible to get 70 miles to the gallon with a Zenith carbureter and crankcase induction. It is claimed that oil was not actually drawn from the base chamber, but the oily vapor suspended in the chamber was made use of. On a 20-hp. Darracq sedan, with four 3.3 x 5.1 in. cylinders, Cozette covered approximately 36 miles to the American gallon. In this case small quantities of oil were drawn from the base chamber, and after being vaporized in the exhaust manifold were passed into the intake manifold. No data is available to show exactly how much oil was consumed with this arrangement, but the engineers claim that the increase was not excessive. In certain cases, as, for instance, with engines having leaky crankcases, the normal oil consumption is hardly increased at all, for aspiration from the base chamber eliminates most of the leaks.

On the night before the competition the Solex Carbureter Co. protested against crankcase aspiration. Charles Faroux, the technical member of the jury, who had authorized this, withdrew, and allowed the remainder to vote, when a decision was given against allowing any air to be drawn from the crankcase. Zenith replied by withdrawing, thus pulling out of the competition a large number of De Dion Bouton cars and all the Peugeot machines. Cozette decided to remain in, but was put at a great disadvantage by having to modify everything during the night before the trials. A lot of jealous protests were lodged, one being put in against the Peugeots because they were not full width according to the rules. When the cars had been altered, they were protested because they were not stock models.

Arrangements to insure accuracy and prevent cheating were admirable. It was not allowed to use the standard tank, but instead a special receptacle had to be mounted either on the outside of the body, or inside when sedan bodies were used, so that it was always under the view of the observer, and had no hidden pipes. The course was divided into hundred yard sections, with official observers on each, as well as regular troops. After the tanks had been filled the cars were kept under military guard for the night and were pushed out to the starting line, where they were cranked by hand, for electric starters had to be either entirely dismounted or put out of commission. An observer connected with a rival firm was placed aboard each car and kept count of distance covered. As the course was marked off by posts at 100 yd. intervals, it was an easy matter to calculate the distance.

High compressions were common, and in some cases oil consumption was high. The Voisin sedan, with sleeve valve engine headed the list in this respect with a consumption of 1½ gal. of lubricating oil to cover 79 miles, while the gas consumption for the same distance was only 2.75 gal. The companion open Voisin consumed slightly more than half a gallon. One-fifth of a gallon was used by the Bignan-Sport sedan to cover 67 miles. All the others used extremely small quantities of lubricating oil.

New Coolant Circulating Pump

THERE has recently been installed at the Cleveland plant of The Steel Products Co. a number of Ross "two way" centrifugal pumps for delivering oil or water to drill presses, lathes, tapping machines, centering machines, screw machines, etc. One pump provides a ⅜-in. stream for six high-speed drill presses. Another handles the supply for twenty-one high-speed drill presses, a third handles six tapping machines, a fourth six centering machines, etc.

Where a battery of machines is cared for by a single pump, a reservoir with an overflow is placed in the main distributing line, thus providing gravity feed for normal use. When pressure is required the overflow may be plugged.

One advantage claimed for the Ross pump is that it needs to be primed only when installed. The pump is designed to deliver a flow of liquid from the same outlet regardless of direction of rotation of the impeller blade. This is required for machines which run in both directions, such as screw machines.

The pump has oilless bearings and graphite asbestos packing, and no bearings or gears come in contact with the cooling fluid. This feature is very important, as steel chips are carried along by the compound. The impeller consists of four light pieces of vanadium spring steel and is designed so that there is no end thrust. The gear ratio is four to one, giving a high impeller speed when belted to a slow pulley.

A New Transmission Designed to Facilitate Gear Shifting

Secondary clutch completely disconnects the transmission from propeller shaft during interval of gear shifting. Shifting is accomplished by imparting a rotary motion to a slotted camshaft in gear box which actuates the shifting yokes. Shifting lever mounted on steering column.

A TRANSMISSION gearset which has been under development for the past several years is now being put into production and is being offered automobile and truck manufacturers. A number of advantages, including a great increase in the ease of gear shifting, and absence of clash, are claimed. In place of the ordinary type of gear shift lever, an accessible steering column control is provided. Increased engine flexibility and increased fuel economy are also claimed to result from the use of this gearset, the former from the particular construction of the gearbox and the latter from the possibility of operating under more advantageous gear conditions.

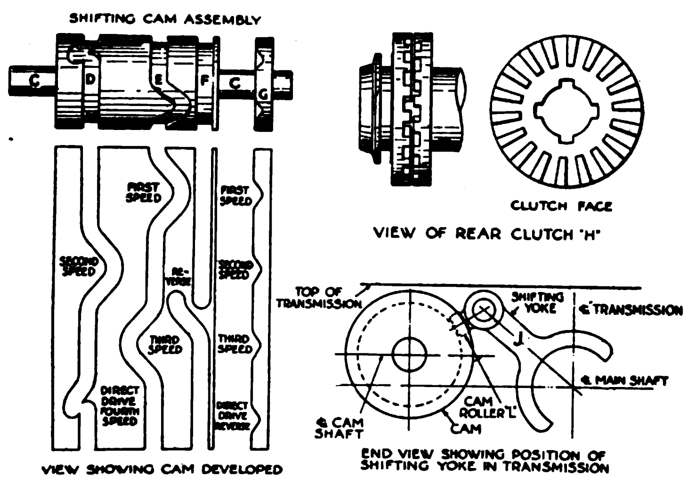

Fig. 1—Details of Flexo transmission gearset, whose operation is described in text.

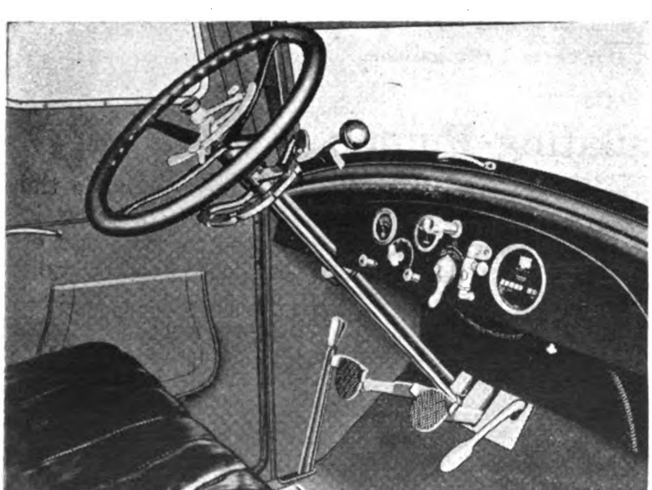
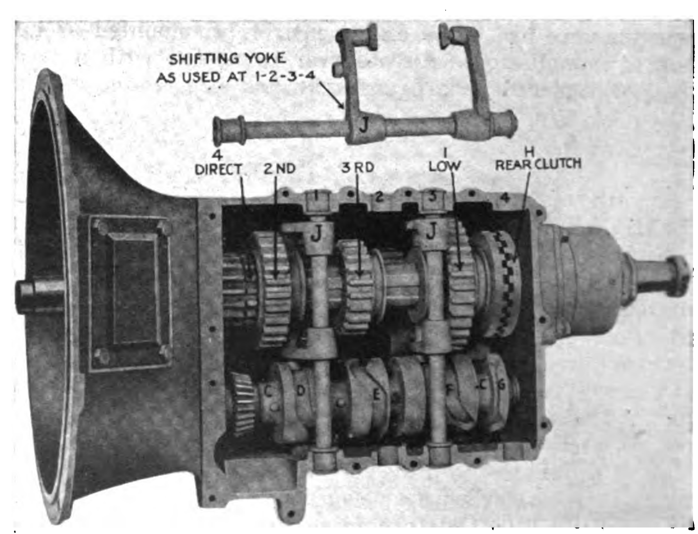
Elimination of the gear-shift lever is made possible by the use of a secondary clutch of the jaw type within the gearbox itself by which the gearset is completely disconnected from the propeller shaft. The driver makes all gear changes by giving a slight motion to a wheel or lever on the steering post, as a result of which the rear or secondary clutch is automatically operated and the gears are shifted while relieved from load and positive drive. Because the gearset is thus unloaded at both ends by the usual power transmitting clutch and by the secondary clutch in the gearbox, it is possible to shift from any gear to any other gear desired, either forward or back, without the use of brake or accelerator. It is claimed that any desired shift can be made instantly, irrespective of roads, loads, grade and brake conditions, speed of engine, car speed and direction.

The gearshifting means also operates the secondary clutch. The device consists of a rotary camshaft, which is so timed that the gears do not begin to shift until the rear or secondary clutch is entirely disengaged. After the gears are completely meshed, the rear clutch automatically re-engages. The device, therefore, is positive in operation.

One of the important advantages claimed for the Flexo transmission gearset is better control of the gear or truck on steep grades or on slippery roads, because of the possibility of using the engine for a brake through the lower gears. With the usual sliding, selective transmission it is difficult to shift down from the higher to the lower gears. With the Flexo gearset, because of the unloading feature, it is possible to make this down shift just as readily as an upshift, and by



Peerless car equipped with Flexo transmission showing lever on steering column for gear shifting.



Assembly of the Flexo transmission showing details of parts.

using the engine as a brake, the tendency to skid on slippery roads is overcome. It is also claimed that the use of the device makes it possible to shift gear more quickly and hence with less loss of car momentum.

In making a shift to a lower gear when climbing a hill, it is ordinarily necessary to first allow the speed of the car to decrease very noticeably. Expert drivers are able to make this down shift at high speeds by speeding up the engine before disengaging the clutch while the gearset is in neutral. However, this requires a degree of skill beyond that of the average driver. With the Flexo transmission, by the use of the secondary clutch, the change down is made while the gears are stationary and unloaded, and consequently no clash is experienced.

This transmission is provided in a three-speed type, and also in types with from four to seven speeds. It is claimed that with the greater number of speed changes a smaller engine can be used and operated within a small speed range. The seven-speed transmission is particularly recommended for trucks.

Referring to Fig. 1, the operation of the transmission is apparent. By means of the hand wheel or lever on the steering post, a rotary motion is given to the camshaft C. On this shaft there are three slots, D, E, and F, which actuate the gear-shifting yokes J, J, J, and a face cam G. As shaft C is rotated, the yoke operated by cam G disengages the rear clutch H, thus completely disconnecting the transmission shaft from the rear drive shaft. As the camshaft C continues to rotate the particular set of gears corresponding to the speed desired is moved into mesh.

Cam G is so timed in relation to slots D, E and F that the rear clutch H re-engages after the gears are completely meshed.

The transmission is known as the Flexo and is manufactured by the Flexo-Motive Corporation.

Some New Automobile Accessories

An Eccentric Type Bonnet Lock

A NEW engine bonnet lock of the eccentric type, herewith illustrated, is claimed to permit of the use of a much stronger spring than is used on the present type of lock and still be readily operated with one finger. The eccentric locking element is associated with the bonnet catch in such a way that a two-point bearing of the same is secured, the intention being to prevent rattling and side motion of the bonnet.

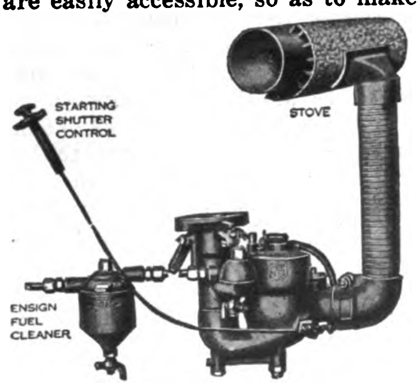
The bonnet lock is adjusted by rotating the body on the anchor bolt. This lengthens or shortens the lock, as desired. Each time the lock is released the anchor bolt is automatically forced into engagement with an absorbent oil saturated pad, contained within the lock body. This lubricates all moving parts.

All exposed parts of this lock are made of brass and nickel-plated. This lock is made in two styles, one with coiled spring and the other without. The anchor bolt is threaded down into the body, giving an adjustment of 1 in., to permit of holding the bonnet down with any desired tension. The lock is manufactured by the Ideal Brass Works.

New Carburetor Model

A NEW carburetor, known as Model E, having manual starting control and new idling adjustment, is announced by The Ensign Carburetor Co. The metering and mixing principles peculiar to the Ensign design are retained, but the adjustments are placed on the top of the carburetor where they are easily accessible, so as to make installation and adjustment as convenient and simple as possible.

The closing of the starting shutter (pulling out the choke, as it is known to most motorists) creates a greater whirling action in the mixing chamber, in proportion to the amount the shutter is closed, even at slow engine speeds. This imparts a higher velocity to the charge and thus more thoroughly breaks up and atomizes the mixture even at starting speeds.



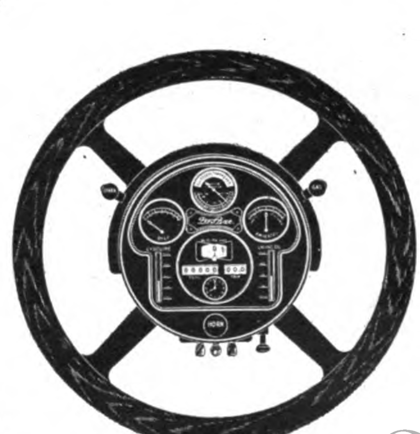
New Model of Ensign Carburetor

Eccentric type bonnet lock

Clearing the Instrument Board

AN instrument board for installation on top of the steering wheel has been developed and is being manufactured by the Whyte-Duffield Mfg. Co. The speedometer, oil gage, ammeter, ignition and lamp switches and any other indicating mechanism normally used in car operation may be mounted upon it, leaving the space ordinarily used for the instrument board and its connections free for storage compartments for gauntlets, lamp bulbs, spark plugs, curtains or any of the numerous other things that motorists like to carry on the car in a handy place. The control board is flush with the steering wheel, and all of the indicating devices are directly in the line of vision of the driver, which is certainly a convenience.

The Whyte-Duffield Mfg. Co. plans to furnish anufacturers with the wheel and post as a complete unit, fully wired, ready for installation. The design is said to possess advantages from the standpoints of both the manufacturer and the repairman.



A Steering Wheel Instrument Board

Tractor Tests Under New Rules Insure Comprehensive Results

The rules of the Fargo tractor demonstration, to be held next week, require that each tractor and horse outfit plow a 10-acre plot. Results will record the average performance of all the tractors. Factors considered will include fuel, lubricating oil and water consumed, stops, repairs, etc.

RULES for the series of three farm tractor demonstrations to be held during the present season have been issued by the National Implement & Vehicle Association's demonstration and show committee. The first is to be held at Fargo, N. D., June 28, 29 and 30. Tractors and horses are to meet in the demonstrations, which are intended primarily to arrive at some accurate figures of farm cultivation with either horse or tractor in order to counteract the mass of misleading information on this subject that has been in circulation for so long a time.

The rules are immeasurably superior to any previously used by the N. I. V. A. in its demonstrations. First, each tractor or horse outfit has a 10-acre lot that has to be plowed, disked and otherwise prepared for seeding. This is the first time that each tractor has been given so comprehensive a test. It will take a three-plow tractor approximately 10 or 12 hours to plow such a tract, which means a full day's work, which is much more of a test than the hour or so that each tractor has had to spend in plowing in the past.

Second, while at its work of plowing, preparing the seed bed and sowing the seed there will be two observers watching each tractor. One is to keep record of the tractor, including such matters as time, fuel, oil, feed, water, labor and other expenses, and the other observer will watch the work done, checking depth of plowing, contour of furrow, width of plowing and any irregularities in the work.

The observers will be appointed by the tractor makers competing and will follow the traditional contest rule of not observing on the make of tractor that they are employed with. These observers will have report cards on which all observations will be noted. It is the first time that observers have been used in connection with tractor tests conducted by the N. I. V. A., although they have been used in tests conducted by different state authorities.

The demonstrations are to be open to tractors of all sizes and to plow outfits consisting of any number of plows and each tractor has to cultivate completely a 10-acre tract irrespective of the number of plows it pulls. A tractor pulling eight plows has no more land to cultivate than one pulling two plows or one plow. This seems to be the unfair character of the test as naturally a two-plow tractor will be working nearly four times as many hours as a tractor pulling eight plows. The small tractor has four times the possibility of mechanical troubles and in reality gets four times as long a test.

This is the first N. I. V. A. demonstration in which a complete record is to be made not only of the fuel consumed by each tractor but also the lubricating oil consumed and also the water consumed in the radiator, in the air washer and in being fed direct to the cylinders through the fuel. A record will be kept of all tractor stops, and in making necessary repairs on the tractor no one will be permitted to perform the work except the driver under penalty of disqualification, and he is only permitted 30 minutes at any one stop for a repair. A stop in excess of this brings disqualification. Tractors are to be limited in speed to that at which they do good work, disqualification being the penalty for traveling too fast for satisfactory work.

The tractors will be required to begin plowing at 8 a. m. opening day and with an hour out for lunch will work continuously until 7 p. m. and on the second and third days will start at 7 a. m. and with an hour for lunch continue until 7 p. m. This will give the tractors a real test and give spectators a real opportunity to observe the different machines. It is just such a demonstration as this that has been needed for many years.

The findings and results of the demonstration are to be of a collective or group character rather than with regard to individual tractors. No tractor will be a winner in the two-plow, three-plow or any other class, but the results of all tractors qualifying are to be averaged and will show what it costs to plow, cultivate and seed a 10-acre tract by tractor and what it costs to do the same work by horses.

In arriving at these results what is known as a supervisor's committee has been appointed which will take the cards made out by the observers and make the necessary calculations from these. These calculations will be made for all of the tractors, and they will be totalled and averaged so that if 60 different models of tractors competed the cost of the work will represent the average of these sixty and not the cost of any one tractor, or any class of tractors, the object aimed at in the test being to give figures on costs that should be reliable. The average costs for the horse outfits will be similarly arrived at.

These results as obtained by the supervisor's committee will have to be referred to the demonstration and show committee of the N. I. V. A., which is the final authority and which approves of all results before they are given out and which also rules finally on all questions regarding the rules and questions arising out of them.

The individual tractor manufacturers are not to be permitted to publish the performance of their tractors until after Oct. 1, 1921. The time required by any tractor to plow, cultivate and seed its 10-acre plot will remain a secret until that time, the apparent reason being that two other demonstrations are to be made and no individual results can be published until the series of three tests is complete.

In publishing the results of each tractor test three figures will be given out: First, one cost figure that will give the average cost for the work of all the tractors.

Second, in order to get figures that will be fairer to these tractors that are better than the average, there will be averaged all those tractors that have performed better than the average of the first or total group. In short this means an average of the best half of all tractors competing.

Third: In order to get figures showing the best that tractors can do the performance of the best six will be taken and averaged and this figure given out.

In all three of these cost figures no mention will be made of individual tractors performances and not until after Oct. 1 will the different tractor makers be permitted to make use of the actual records of their machines.

Tractors will be permitted to use any fuel, such as gasoline, kerosene or distillate, but there shall only be one grade of each and this shall be used by all competitors using such fuel. This eliminates the possibility of any tractor using a superior grade of any particular fuel.

In view of the character of representation in this supervising observers committee it seems unfortunate that the N. I. V. A. demonstration and show committee does not let the findings of such an impartial committee be final. The world at large would acccept the findings of such a committee quicker than findings which are approved by a committee representing those tractor makers competing in the demonstrations. The results would carry greater weight and be of more value to the tractor industry if the findings of the supervisors committee were final. The results would then be free from all trade influence. As a great contest take the annual 500-mile Indianapolis speedway race in which the contestants have no say in the findings, but such rest entirely with a disinterested contest committee, made up of men in no wise associated with any of the manufacturers of competing cars, or even with concerns manufacturing parts entering into competing cars or accessories used on cars.

Entries for the Fargo demonstration closed June 21 for tractors competing in the demonstrations, but for those to be exhibited at belt work entries close June 27.

A large accessory exhibit tent is to be used for display purposes, the rent for space in such being $1.25 per sq. ft. An entry fee of $100 is made for tractors; $50 for garden tractors, and $50 for cultivators. Fees are charged for tractors for belt work as well as other for exhibit purposes only.

A New Canadian Truck

A NEWCOMER in the Canadian truck field is the G. & J. truck. This truck has been designed particularly to meet the conditions typical of Canadian transportation and has been under test for about 14 months.

Production of the 2-ton model began on a small scale in the fall of 1920. The designs of the 3½-ton model were put on exhibition at the Windsor, Ont., show in the latter part of February, and this model is now also in production.

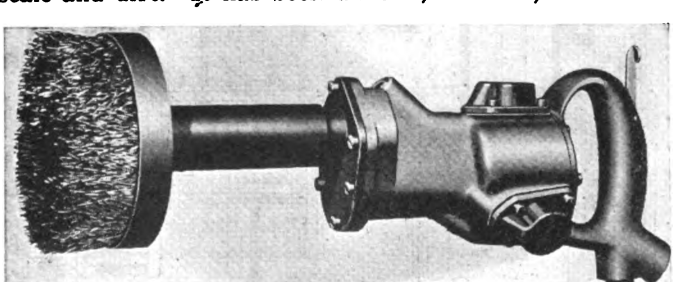
It is also purposed to bring out a light, 1-ton model, and eventually a 5-ton model. The specifications of the 3½-ton G. & J. truck, which is the latest model to be put in production, are typical of the entire line, except the 1-ton, which will be different in every respect, but on which information is not now available. The Hinkley Class B truck type engine in conjunction with the conventional, worm drive, Timken-Detroit axle, gives a foundation for the design of the truck. The engine is 4½ x 5½ in. and develops 50 hp. on the brake.

The other units in the truck include the Brown-Lipe transmission with four speeds mounted amidship on frame cross-members with provisions for a tire pump and power take-off. This transmission is mounted on Timken roller bearings and employs nickel steel gears throughout. Spicer propeller shafts with enclosed universal joints are employed, providing a straight line drive from the engine to the rear axle. The frame is rolled channel steel, hot riveted and reinforced with gussets. The depth of the channel is 7 in. and the width of the frame 38 in. The height from the ground to the top of the frame is 35 in. under average load. The road clearance under the front axle is 9½ in. and under the rear axle 9 in. The front wheel tread is 66½ in. and the rear wheel tread 65¾ in. The overall length is 245 in. and the width over the rear hubs is 86¼ in. Other specifications are as follows: Cooling by centrifugal pump and McCord finned tube radiator. Vacuum fuel feed to Stromberg carbureter. Bosch magneto with impulse starter. Dry plate clutch. Chrome vanadium springs. Gear reduction 10.3 to 1 on high, 55.2 to 1 on low. Ross steering gear. Chassis weight 7000 lb. Wheelbase 160 in.

The truck is made by the Gotfredson Joyce Corp, Ltd.

Wire Brush Cleaner

WIRE brush cleaning of metal surfaces offers an opportunity for considerable saving of time and labor over that required by hand in removing paint, rust, scale and dirt. It has been difficult, however, to obtain a wire brush of proper design and materials which would work effectively on an air motor and not wear out too rapidly.



Ingersoll-Rand air driven brush.

A wire brush of very rugged design has recently been placed on the market by the Ingersoll-Rand Company for use with its standard No. 6 "Little David" Drill. It is a brush with face diameter of 5 inches and is made up of wires of a special heat-treated steel.

It is manufactured particularly as an attachment for the No. 6 Drill (as illustrated), this type of machine being especially suited for work of this nature. The whole outfit weighs only 11½ pounds.

The wire brush outfit is adapted for removing paint, rust, scale and dirt from tanks, steel cars, structural steel and all sheet metal surfaces. It is very useful for cleaning iron, steel and aluminum castings.

Intake Manifold Practice in Europe

Poor economy results are frequently due to faulty manifold design. Fuel quality affects manifold performance greatly and renders difficult the designing of a manifold which will be satisfactory under all conditions. Past and present intake manifold practice is discussed in detail here.

By W. F. Bradley and S. Gerster

SPEAKING generally, insufficient attention has been given in the automobile industry to the design and construction of intake manifolds, and it is because of errors in this particular feature that many modern engines give poor economy results. Where mistakes have been made in the layout of the intake manifold, it is useless to attempt to discover a complete remedy by the use of a more modern or more efficient carbureter.

THIS article, by Automotive Industries' French correspondent and a well-known French consulting engineer, is based mainly on French practice. The gasoline sold in France to-day contains less of the heavy fractions of petroleum than does the motor fuel sold in this country. This may explain some of the recommendations made in the article, notably the insistence upon the importance of water-jacketing of the manifold and the slight reference to exhaust jacketing.—Editor.

It is not at all an easy matter to lay out a manifold which will give satisfactory results under all operating circumstances and with different qualities of fuel. If high grade gasoline could always be assured, the task of laying out a manifold which would operate satisfactorily under the wide range of temperature conditions of winter and summer, would not be very great.

With the heavy and poorly refined gases now commonly employed in America, the problem of designing an efficient manifold and a good carbureter is accentuated, and the inconveniences of these low grade fuels soon show themselves in carbonized combustion chambers, dirty valves and plugs, crankcase dilution, etc.

With light, well refined gas there is less necessity for preliminary heating of the mixture, and an increased volume of gas can be introduced into the cylinders. With heavier gasoline, with benzol, and with kerosene, the manifold should be a part of the carbureter, and the mixture should be well heated from the time it leaves the carbureter until it passes through the valves into the combustion chamber. It is even advisable, when using kerosene and benzol, to heat the fuel in the carbureter, and before it passes through the jet. In the case of napthaline the whole appliance must be heated in order first of all to liquify the fuel and then to vaporize it.

Experience has shown that gas velocity V_g

$$V_g = \frac{S' \times V_p}{f}$$

should be between 60 and 70 meters (196 and 230 feet) per second at the carbureter outlet. In the above formula S' represents the surface of the piston, V_p the piston velocity and f the section of the gas passage. Variations in the gas velocity occur according to the length and shape of the pipe, it generally being admitted that the velocity at the valve ports should be from 56 to 62 meters (183 to 203 feet) per second.

Intake Pipe

There is every advantage, in a single cylinder engine, to have the intake pipe as short as possible. In a four-cycle engine gas admission takes place once, and during

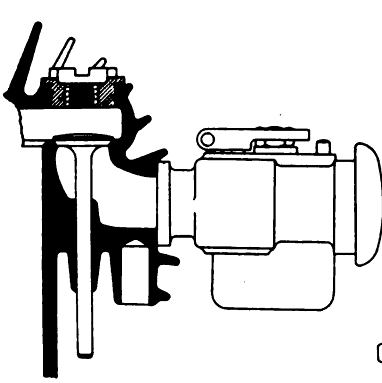


Fig. 1

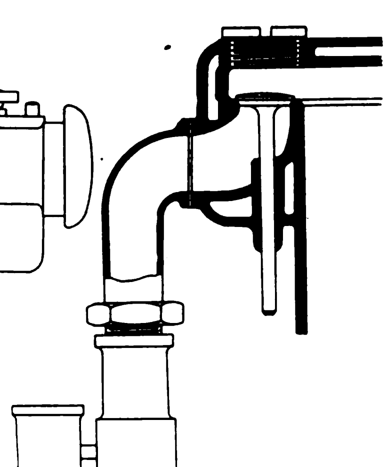

Fig. 2

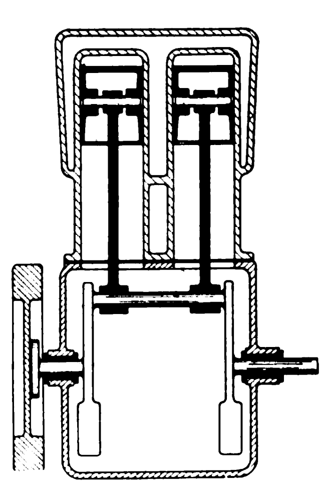

Fig. 3

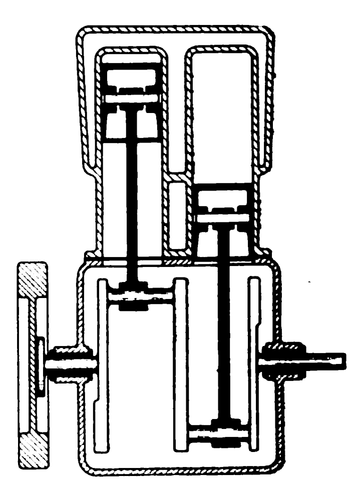

Fig. 4

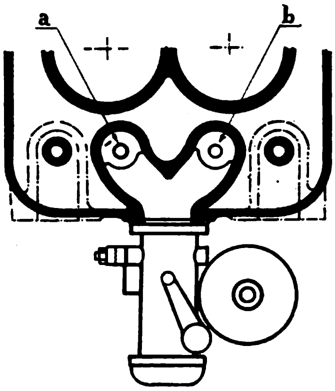

Fig. 5

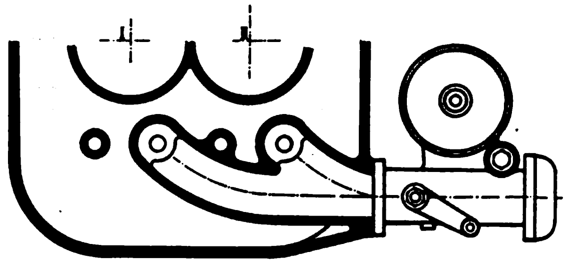

Fig. 6

a half revolution of the shaft, for two revolutions of the engine. In other words, during three-quarters of the time parts of the manifold are filled with gases which have been arrested by the closed valve. The greater the volume of gas, the greater the condensation, and this condensed gas is admitted into the cylinder without being mixed with air, and naturally burns badly. It is in order to avoid this that the intake pipe should be made as short as possible, or even better, the carbureter should be bolted up direct to the cylinder, as shown in Fig. 1.

When only vertical carbureters were in use the problem was rather different, for in order that the mixture be formed it was necessary to have a curved pipe from the carbureter to the intake port (Fig. 2) and it was advisable that the curve be made as easy as possible. A much higher efficiency is obtainable with the arrangement shown in Fig. 1 than with Fig. 2.

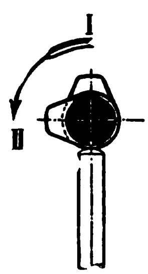

Fig. 7

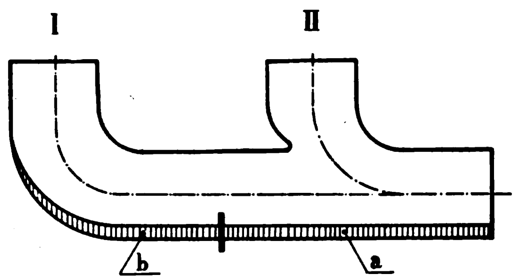

Fig. 8

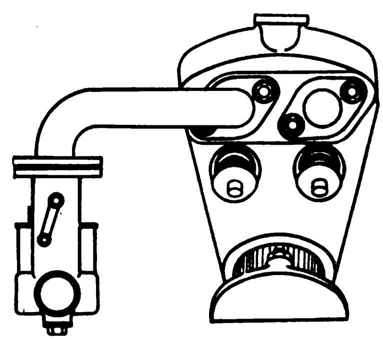

Fig. 10

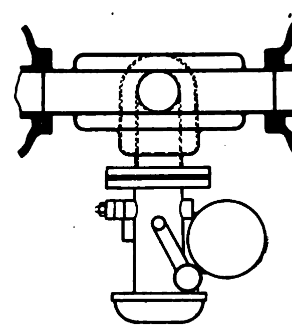

Fig. 11

Twin Cylinder Vertical Engine Practice

For twin cylinder vertical engines the type of manifold varies according to whether the throws are at 360 degrees (Fig. 3) or at 180 degrees (Fig. 4). With throws at 360 degrees the manifold should be laid out according to Fig. 5, (a) being the valve of the first cylinder, and (b) the valve of the second cylinder. It is advantageous to have an internal intake manifold, surrounded by the circulating water, the heat thus obtained being sufficient to maintain the gases at a sufficient temperature to prevent condensation. On some engines with thermo-syphon water circulation and inclined to run rather hot, this heating may be excessive in summer but in winter it gives every advantage.

The manifold of a two-cylinder engine with throws at 180 degrees, as shown in Fig. 4, should not be dealt with in the same way, for there are not the same intervals between the two aspirations as in an engine with cranks at 360 degrees. The length of time during which the gases remain still in the intake manifold is not the same for the two cylinders, and, in consequence, there is condensation for the cylinder which aspires after the interval, while the second cylinder, aspiring immediately after the first, is not affected by condensation. Fig. 6 shows a suitable type of manifold for an engine of this class, and Fig. 7 is the camshaft with the order of gas admission.

In this case cylinder 2 is the first to aspire, cylinder 1 coming immediately after it. During two revolutions of the engine the carbureter supplies a mixture to the succeeding cylinders at intervals of a half revolution, and during the rest of the cycle it is inactive.

During this revolution there is partial condensation of the mixture remaining in the intake manifold, and this condensed gasoline is drawn into the cylinder which is the first to aspire after the interval. If the manifold is laid out according to Fig. 5, the first cylinder to aspire after the interval will have a rich mixture. If the manifold is according to Figs. 6 and 8, either one cylinder will have a richer mixture than the other, or the two will have the same mixture, according to the order in which they aspire. If cylinder 1, Fig. 8, takes the first aspiration, it will receive the gasoline condensed at points *a* and *b*, while cylinder 2, aspiring immediately afterwards, will get no condensed gasoline, and consequently will have a weaker mixture. On the other hand, if cylinder 2, on Figs. 7 and 8, is the first to aspire, it will only take up the gasoline condensed at points *a*, while the liquid fuel at *b* will be drawn into cylinder 1.

This, therefore, should form the basis of the firing order for engines of this type, as well as for four, six and eight cylinders in line with one or several carbureters. This matter can readily be controlled on an engine with an external unheated manifold, when it will be found that the two cylinders will stand quite a different carbureter

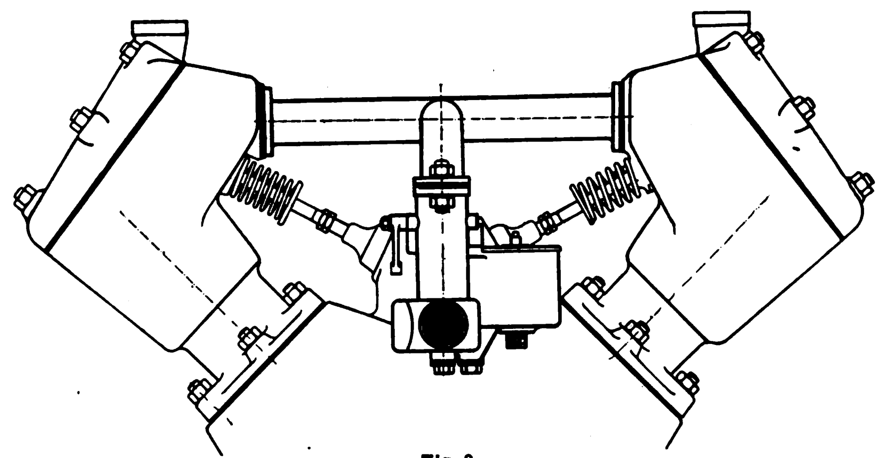

Fig 9

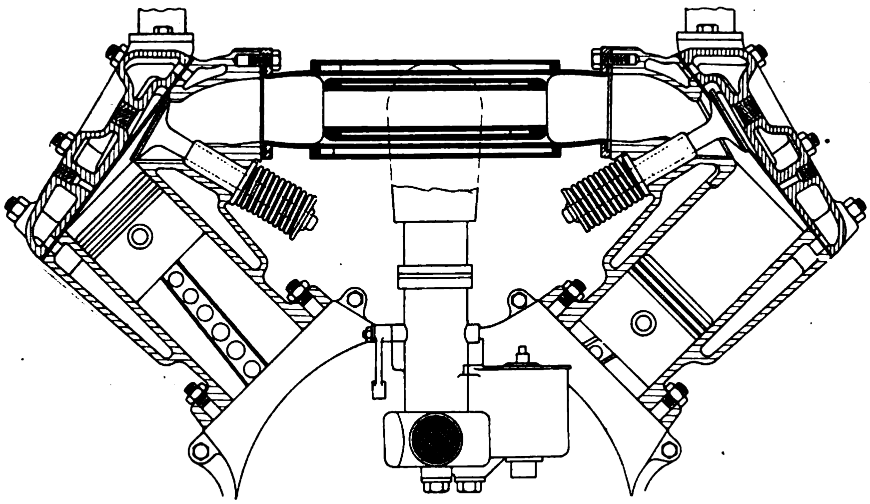

Fig. 12

very defective manifolds. An example of this is given in Fig. 13, where the long unheated pipe above the carbureter tends towards excessive condensation, and the pocket above the valves completely upsets the mixture. With an intake manifold of this type it is impossible to get slow running, and starting in winter is always difficult, for there is insufficient gas velocity to carry along the liquid fuel deposited in the pipe. Another old type, but still in use on some cars, is shown in Fig. 14. This has many defects, notable among them being the point (b) where fuel condenses, making starting and slow running difficult.

With a manifold of this type an improvement is obtained by the device shown in Fig. 15. The large diameter tube *a* carries air only, the rich mixture being taken through the small diameter tube *c* as far as the point where the branches are formed for the different valve ports. In addition to this, the part *d*, where there would normally be a tendency for fuel to condense, is heated by the water jacket.

Very few, if any, engines are now built with external carbureter on the opposite side to the valves, for better results can be obtained, by reason of the shorter pipes, with the carbureter on the valve side of the engine.

The manifold indicated in Fig. 16 has all the inconveniences of the unheated external manifold for twin cylinder engines shown in Fig. 5, for one of the cylinders in each group is always more richly supplied than the other. Fig. 17 gives a type of intake manifold suitable for an engine with separate cylinders.

Firing order should be 2-1-3-4, in accordance with the theory illustrated in Fig. 8. In this way cylinder (1) can receive gas of the same richness as cylinder (2), and the same applies to cylinders 4 and 3. With the lay out shown in Fig. 16 this is impossible.

The adoption of block cast cylinders has contributed considerably to the improvement of intake manifolds. For-

setting than would be required under other conditions.

When the whole of the intake manifold is inside the water jacket there is much less tendency for gasoline to condense and little trouble is experienced in this connection. Twin cylinder V-type engines, with carbureter and intake manifold mounted as in Figs. 9 and 10, are particularly susceptible to the defects mentioned above, and various devices are adopted to overcome these, without complete success, however.

With an intake manifold as shown in Fig. 11, the same defects are encountered as in twin cylinder vertical engines at 180 degrees, shown in Fig. 4, with the intake manifold of Fig. 5. Some improvement is obtained by water jacketing the manifold, as shown in Fig. 11, or by having a fairly long vertical branch, as indicated in Figs. 9 and 10. Another type of manifold is shown in Fig. 12, where an internal tube balances the two columns of gas and prevents condensation.

Old Types

Many old type four-cylinder engines still in use have

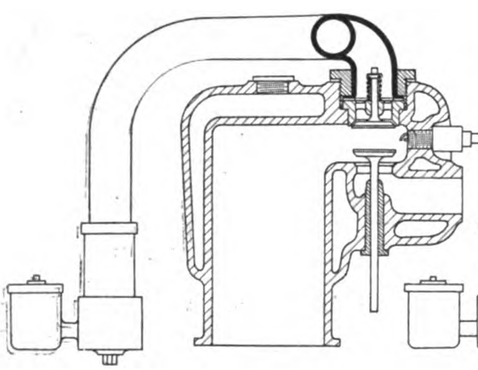

Fig. 13

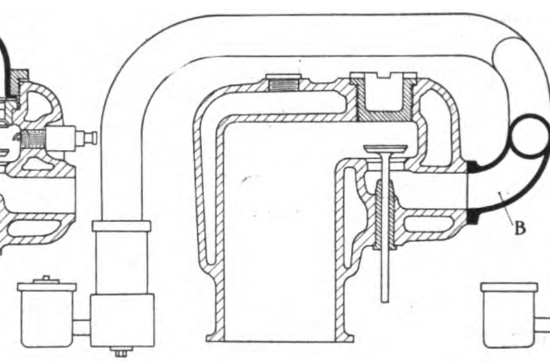

Fig. 14

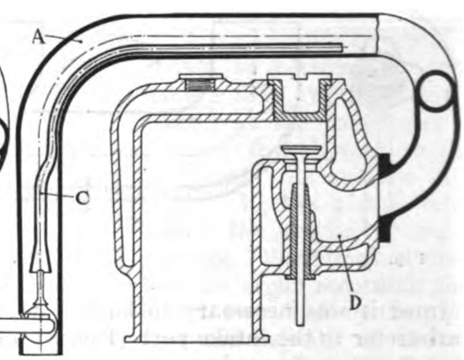

Fig. 15

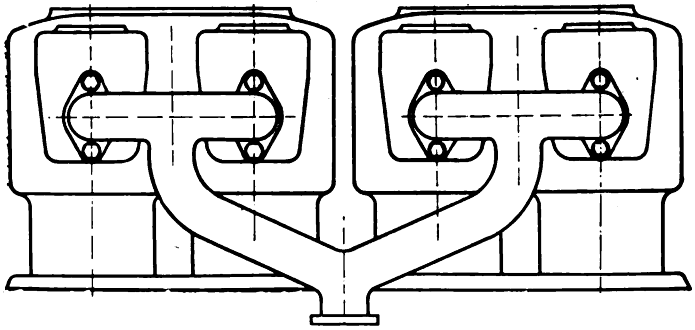

Fig. 16

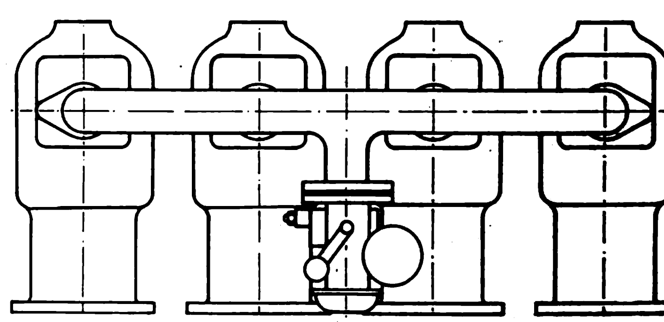

Fig. 17

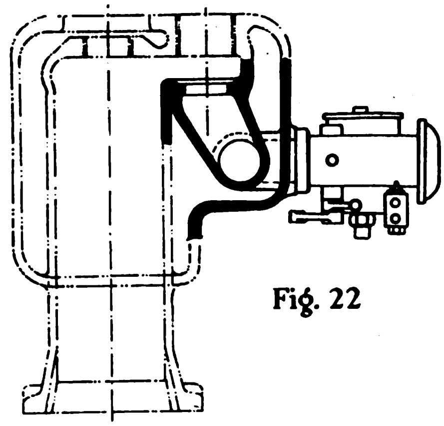

Fig. 22

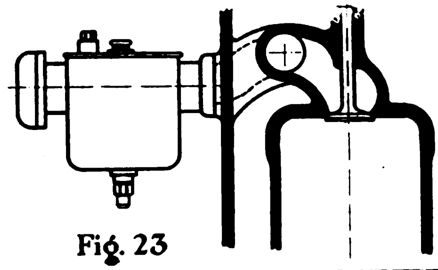

Fig. 23

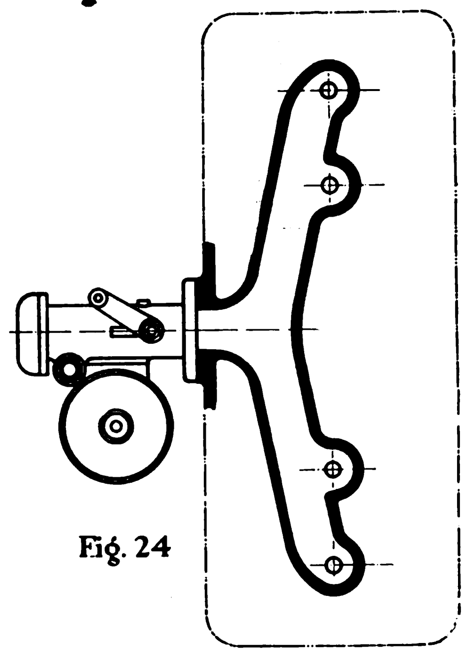

Fig. 24

merly the heating was secured by a by-pass from the circulating water, with pipes of small diameter which were liable to become choked, or with hot muffs from the exhaust, which gave too much heat and frequently failed to operate satisfactorily.

Since the introduction of internal manifolds surrounded by the circulating water the efficiency of automobile engines has been considerably improved. Figs. 18 and 19 show an internal water heated manifold placed externally to the valves. This should be compared with the more satisfactory layout illustrated in Figs. 20, 21, and 22. The manifold in Figs. 20 and 21 is designed for a gas velocity at the carbureter mouth of 230 feet per second, of 220 feet per second at the point *b*, and 210 feet in the valve ports. It will be noticed that the carbureter is placed at the lowest point and the gas takes an upward direction during the whole of its course, so that any particles which may be condensed will be carried along with regularity. Particularly for cold weather service this is a most satisfactory manifold, for the mixture is maintained at a reasonable temperature while in formation and until it passes into the cylinders. The manifold shown in Fig. 22 is certainly an improvement on the preceding one, for the length of the gas passages is reduced.

In order to secure successful and economical operation, the intake manifold should be of uniform diameter and have no sharp bends, and particularly no right angle bends at the valve ports such as are shown in Fig. 13. Sudden variations in the diameter of the gas passage cause expansion of the gases and provoke condensation. A manifold design which has proved satisfactory for overhead valve engines is shown in Figs. 23 and 24.

Six-Cylinder Motor Manifolds

Intake manifolds for six-cylinder motors differ in principle according to the layout of the crankshaft. The two arrangements shown in Figs. 25 and 26 are common practice. The firing order for a crankshaft of the type shown in Fig. 25 can be 1-3-5-6-4-2, or 1-4-2-6-3-5. For the crankshaft shown in Fig. 26 the firing orders are either 1-5-3-6-2-4 or 1-2-4-6-5-3. The order most commonly adopted by European manufacturers is 1-5-3-6-2-4, shown in Fig. 26 followed by the order 1-3-5-6-4-2 indicated in Fig. 25.

In deciding the firing order of the cylinders it is necessary not only to take into consideration the question of the intake manifold, but also the working conditions of the crankshaft. In laying out the order

Fig. 18

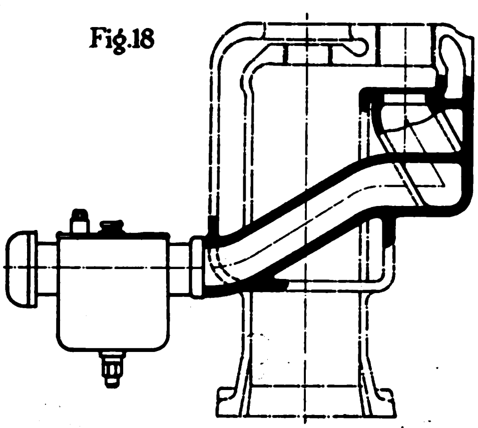

Fig. 20

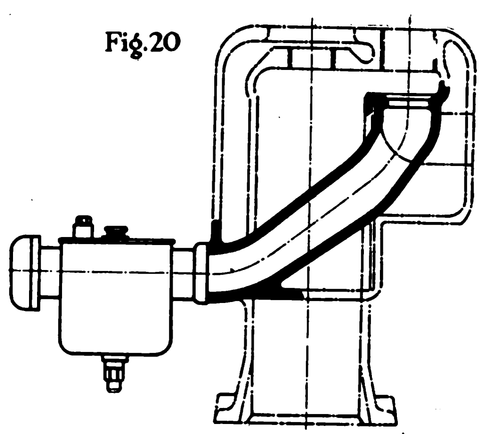

Fig. 19

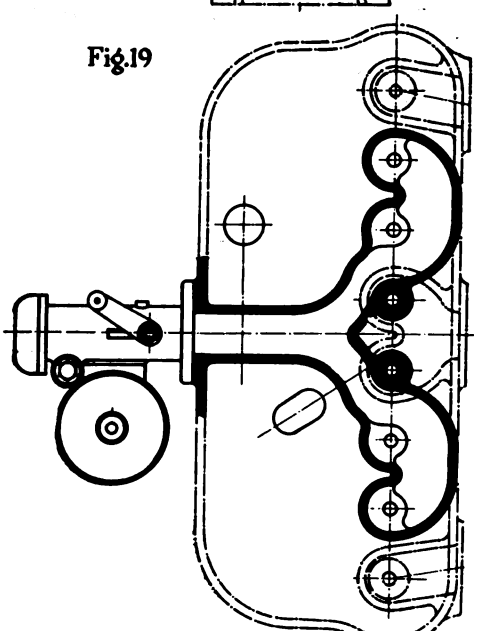

Fig. 21

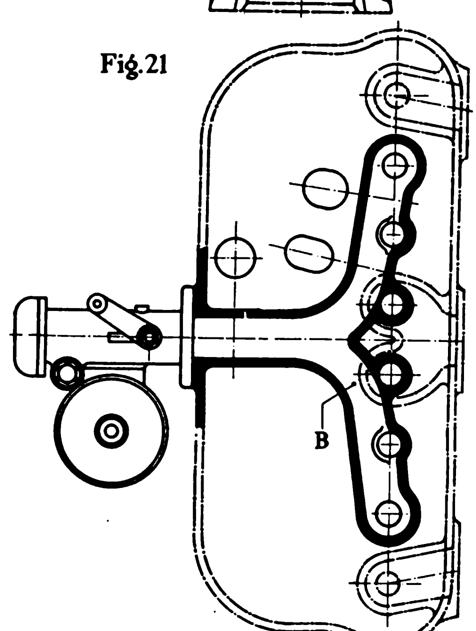

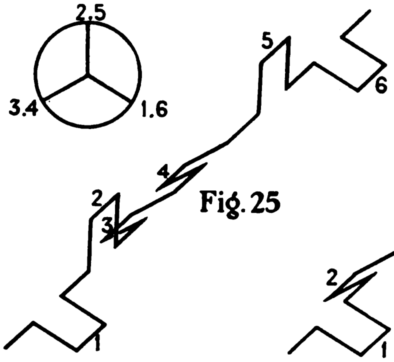

Fig. 25

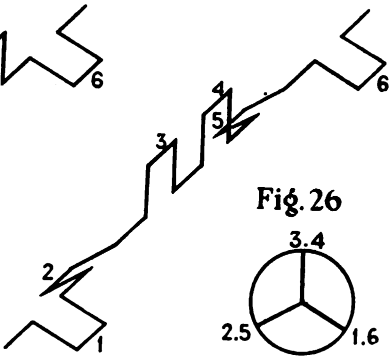

Fig. 26

in which the aspirations shall take place, the principles of condensation of fuel which have been explained in connection with twin cylinder engines at 180 degrees should be kept in mind.

The use is fairly common among European manufacturers of six-cylinder engines of two carbureters, one for each group of three cylinders, these two carbureters either being entirely distinct or having a common float chamber.

Experience has shown that with an external manifold having insufficient heating it is very difficult to avoid slight variations in the composition of the mixture from cylinder to cylinder. The manifolds shown in Figs. 27 and 28, for instance, cannot give good results, for these long pipes cause condensation, and the liquid fuel is always aspired by the same cylinder, which becomes choked with gasoline. Fig. 29 is another defective arrangement, by reason of its two long, unheated branches.

Satisfactory results can be obtained from the manifold shown in Fig. 30, if the firing order is 1-5-3-6-2-4; the flow of gas changes in its direction at each aspiration, the cylinders 3 and 4 then 2 and 5 being fed with the greater facility. This arrangement has been adopted by Delage for his overhead valve sporting type car with external manifold.

Another Firing Arrangement

When the firing order is 1-3-5-6-4-2, the arrangements of intake manifold most commonly adopted are those shown in Figs. 31 and 32, both of which are satisfactory, for they give practically equal lengths of pipe for cylinders 2, 3, 4 and 5. There is a greater length for cylinders 1 and 6, but this does not appreciably affect their operation, for as they are followed by their neighboring cylinders 2 and 5, there is no change of direction of the gas in the manifold. This general arrangement is almost essential when a single carbureter is used. Fig. 33, although found on certain cars, has little to recommend it.

If two carbureters are employed it would be difficult to get a better arrangement than that shown on Fig. 34, which is the general layout adopted on the six-cylinder Hispano-Suiza, the only difference being that instead of two independent carbureters, a double type with a common float chamber is employed.

With six-cylinder engines having internal manifolds it is rather difficult to ascertain what variations are taking place in the supply of gas to the different cylinders, and only a certain notion can be obtained when starting up with the engine cold. For this type of engine two manifold arrangements are common, namely the one shown in Fig. 35 when the firing order is 1-4-2-6-3-5, and the one shown in Fig. 36 with the firing order 1-5-3-6-4-2. For small engines with comparatively small intake pipes, the operation is practically perfect with these two layouts, and it is impossible to detect any substantial varia-

tion in the mixture as between the different cylinders.

Six-cylinder engines with internal manifold and two carbureters can be laid out according to Fig. 37, when the firing order is 1-5-3-6-2-4. This particular layout is adopted by Delage for his stock six-cylinder model with internal manifold. Undoubtedly this arrangement is more satisfactory from an operating and efficiency standpoint than those shown in Figs. 35 and 36, but it is a more costly production job, by reason of the two carbureters and their combined throttle control. Theoretically a single carbureter is preferable, but practice has shown that better results are obtained with a carbureter for groups of three or four cylinders used on a multi-cylinder engine.

Eight-cylinder-in-line engines operate like two four-cylinder engines in line with the crankshafts at 90 degrees and with two carbureters. Generally the manifold of each group is laid out as for a four-cylinder engine. On certain high speed motors use has been made of three carbureters, a small one supplying the mixture for slow running, and two large ones coming into operation together with the small one, at high engine speeds. Fig. 38 shows this arrangement on a European eight-cylinder-in-line engine of 85 by 140 mm. In this engine each group of four cylinders is fitted with a 42 mm. carbureter which feeds through the big intake valves of each cylinder, while the small intake valves of the eight cylinders are fed from a single 36 mm. carbureter through a manifold uniting these eight valves.

It has not been possible to get really satisfactory results on eight-cylinder V engines with a single carbureter. Although it is reasonable to suppose that a single carbureter, as shown in Fig. 39, giving the quantity of gas required for the engine, should enable the same power to be obtained as with two single or one dual carbureter, tests have shown that the dual carbureter arrangement, as shown in Fig. 22, gives the better results.

It is not only necessary to consider gas velocities and the possibility of condensation in the gas passages, which upset the mixture, but account must be taken of changes of direction at the main fork above the carbureter. When the direction of gas flow is changed condensation takes place. As a consequence the mixture distributed to the different cylinders ceases to be uniform, and there are no reliable means of determining which cylinder or cylinders are being ill supplied. These defects can best be overcome by the use of one carbureter for each group of four cylinders, or by a dual carbureter. The preferable firing order is that shown in Fig. 41. The manifold should be water heated.

Review of Engineering Features of British Motorcycles

Vickers, one of the best known British engineering firms, has entered the motorcycle field with a two-stroke V engine for the Enfield machine. Ladies models have been introduced by the manufacturers of several lightweight machines. America well represented in Olympia show.

By M. W. Bourdon

THE entrance of Vickers, the well-known engineering firm, into the motorcycle field and the appearance of several ladies' models comprise two important features of the recent British motorcycle show. Interesting engineering features appeared on a number of models, while changes in the method of lubricating two-stroke engines are common.

The Vickers entry thus far consists only of a twin-cylinder V engine for Enfield machines. Several other prominent British car manufacturers have also become interested in the motorcycle industry. Chief among these are Sunbeam, Humber and Rover, though these are all firms which graduated into the automobile industry from the manufacture of pedal cycles. The designers of their motorcycles are chiefly the men who were responsible also for their present pedal bicycles.

Several makers of lightweight machines have introduced a lady's model. The frame is not looped as in ladies' pedal cycles, but merely has the top tube inclined considerably so that it runs into the saddle tube about midway in the length of the latter. Motorcycling, not only on lightweights, but also on some of the heavier side-car machines, is becoming increasingly popular among women of all classes and of ages well into and often beyond the forties. A woman riding a man's machine occasions no remark, but while some makers, therefore, decline to standardize a special model, others believe that a wider field will be exploited by doing so.

Business in the British motorcycle industry was extremely slack during the two months preceding the November show at Olympia, but it has never for a moment been suggested that this has been due to the market having reached a state of saturation; it has been felt that orders were being held in abeyance for two reasons (1) an anticipation, or rather a hope, that a general reduction in prices would occur on the opening of the show, and (2) a doubt as to whether or not any radical changes in design would be in evidence in 1921 models. There has been no ground for either; prices have barely fluctuated, decreases and increases having occurred only in isolated cases, and even then have been small, while in the case of established makes variations in design have not been pronounced.

With certain exceptions, to be referred to later, the results of the past 12 months are, therefore, very disappointing from an engineering point of view. Improvements in detail were to be seen on almost every stand, but development in general has hardly occurred; in fact, there are not a few individuals, whose opinions are worthy of some respect, who maintain that development in certain directions has gone too far in the present-day motorcycle. The latter has been increased in power and speed and improved in suspension and equipment until, with a side-car attached, it has become as weighty and cumbersome as a light, two-seated, four-wheeled car, without the cleanliness of outline, ease of cleaning and protection of the occupants and power plant afforded by the latter. Further, in economy of running it provides little or no advantage over the miniature four-wheeler, which frequently covers 50 miles on an Imperial gallon of fuel, a consumption no more than equalled by some of the big side-car outfits. In speed and hill-climbing abilities only do the latter excel.

There were, however, at Olympia two machines which contain the germ of an idea for a new type of motorcycle for general purposes, a solo machine primarily, but one capable of carrying two passengers tandem fashion. At present the two machines in question are little better than glorified scooters, but though they differ very widely in constructional details, both contain the fundamentals of a practical type, with a screened engine. completely sprung frame of simple design, concealed controls and, generally, a motorcycle with many of the characteristics of a car. Further and detailed references to these machines and their possibilities of development occur later in this report. Meanwhile, dealing with the motorcycles as one found them at Olympia, a very pronounced tendency brought out by the show as a whole is the increasing popularity of lightweight machines, thus continuing a tendency which commenced about 1913. While there is no generally recognized definition of a lightweight motorcycle in Great Britain, it is usually assumed to be one having an engine of less than 15 cubic inches engine capacity, but, strictly speaking, this classification is misleading, for many machines of less than that capacity are outside the pale in weight.

Lightweights and Taxation

The popular type of lightweight is one weighing less than 200 lb., and there have been marked endeavors recently to lower the weight here and there so as to bring machines previously weighing over 200 lb. within that figure. These endeavors have been encouraged by the fact that on January 1 the new scale of automobile taxation comes into force, and in respect of motorcycles this will render machines under 200 lb. liable to an annual tax of $7.50, whereas machines over 200 lb. will be taxed $15. But the true lightweight machine is well within the maximum, and in its simplest form—namely, with a two-cycle engine of about 2½ hp., single speed belt drive and 24 x 2½-in. wheels—is less than 150 lb.

But while an increasing number of manufacturers are standardizing a lightweight model, none has discarded heavier and more powerful single- and twin-cylinder types. In fact, some have increased their range by adding a 6- to 8-h.p. model with twin-cylinder, 50-deg. Vee or horizontally opposed engine. For instance, Rudge has come out with a new Vee-engined model with all-chain drive.

There is a tendency to strengthen up some of the larger lightweights originally intended for solo work to make them suitable for light side-car attachments. It has been found that users of lightweights persist in fitting side-cars, so several makers have thought it advisable to recognize this fact and strengthen the frames to render them more suitable for passenger work.

Scooters and Motorized Bicycles

Although the motor scooter has not appealed to the public to an extent justifying the ambitious output plans of the number of firms who introduced them in 1919, it has had a certain vogue and was represented on five stands at Olympia. A seat is now general, but as a type no development has occurred, except in the cases already mentioned.

Motorized bicycles and pedal cycle motor outfits are in evidence. Of the former the J. E. S. has a stiffened frame, spring forks and a 1½-h.p. engine, both two-stroke and four-stroke types being used, the latter with superimposed valves. They have a direct belt drive to the back wheel with a jockey pulley for belt adjustment. In motor outfits, the Simplex unit has a 1-h.p., horizontal, two-stroke engine and a combined fuel and oil tank mounted as a unit on two pairs of tubular stays over the rear wheel, with a chain drive to a large sprocket secured either to the wheel spokes or rim. A single speed only is provided, with a hand-operated friction clutch within the driving sprocket.

Standardization Lacking

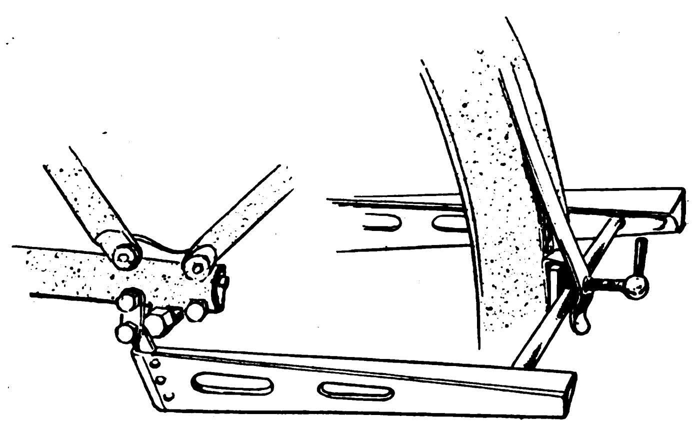
There is no evidence of real endeavor to reduce the production costs of any of the big range of types made by British firms, and there is no indication of any co-operation to standardize either frames or wheels, and no increased use of stock engines or gear-sets. The majority of firms make their own engines, only 38 per cent of the latter being stock jobs. Percentages are reversed in the case of gear-sets, and 55 per cent are of stock type. In four-stroke engines the most popular stock make is the J. A. P., which is supplied in many sizes; in two strokes the Villiers is favored. Of gear-sets, Sturmey Archer supplies 80 per cent of those that are not made by the motorcycle manufacturer. Spring front forks are frequently stock designs, but no other main detail is standardized. Frame design is still very involved and costly; no development in pressed steel frames has occurred since the introduction of the Pullin, described in AUTOMOTIVE INDUSTRIES last summer. There are three or four firms who specialize in the production of frames; but the latter are not stock jobs; they are made by these specialists to the design of small assemblers, each of whom has his own ideas concerning shape, size and general lay-out.

Rear springing for frames is developing very slowly, and designs are usually distinctly complicated and costly to produce. There is no observable endeavor to cope with heavier fuels, and a large proportion of standard machines, even new models, have no provision for heating either the air or the carbureter, except the proximity of the latter to the cylinders. Brakes are improving slowly, but there is still plenty of scope for further development; the same applies to the mudguarding of the smaller solo machines, though in the larger types and in side-car outfits guards run up to 8 in. in width.

Flexible Side-car Attachments

In side-car design there is very little development to report as compared with twelve months ago. There is, however, a tendency to provide a flexible coupling between the cycle frame and side-car chassis in order to prevent broken frame tubes owing to the stresses imposed through the side-car chassis from its wheel. This aim is attained by Beardmore by connecting the side-car axle to the frame through the medium of a short, laterally arranged laminated spring which displaces a section of the usual steel tube; upon the axle the body is mounted with Cee springs, intervening in the usual way, the front part of the body being spring mounted on the rigidly supported chassis. Two-seated side-cars (tandem or side-by-side seats) are now rarities.

Side-car taxicabs are now running in three British towns, Birmingham, Nottingham and Glasgow; the standard side-car machine is used usually with an 8-h.p. Vee twin engine, but a special two-seated body is fitted with a sedan or folding top.



Pressed steel rear stand of Beardmore machine

No maker has yet standardized electric lighting, but practically all of those producing machines over 3 h.p. and several of those making smaller types are prepared to fit a dynamo lighting equipment at an extra charge. When electric lighting is used a combined magneto and dynamo is becoming popular, two of the most widely used outfits being the Lucas Magdymo, which has two armatures, and the M-L Maglita, which has one armature generating the lighting current and a stationary ignition coil in the magnetic circuit.

An addition has been made to the names of important engineering firms associating themselves with motorcycle production. B. S. A. has for many years made complete machines; the show of 1919 saw the introduction of the Beardmore 3½-h.p., two-stroke machine with a number of novel and commendable features, such as the use of pressed steel for a fuel tank forming the top member of the frame, unit power plant and laminated springs, back and front.

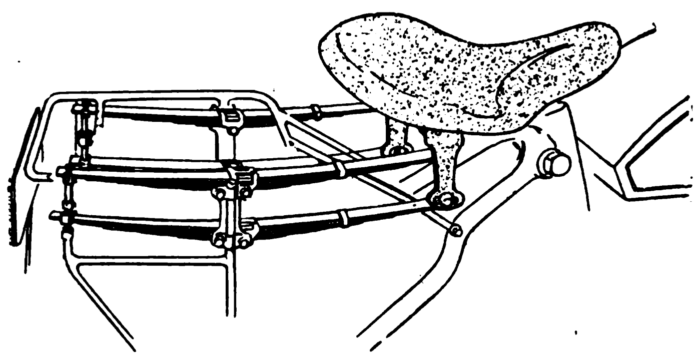
Individual and Aggregate Outputs

The great majority of British makers of motorcycles are quite small firms who consider they have done well if they reach an output of 300-400 per annum. There are only two whose output is believed to approach five figures; namely, Triumph and Douglas, both having probably turned out a similar number since last show, approximately 8000 machines each. But as with cars, so with motorcycles, British makers are very secretive concerning outputs. It is estimated, however, that the

aggregate number produced during 1920 will be approximately 50,000 from all plants, which averages, roughly, 500 each.

Engines

Dealing specifically with the engineering features of British motorcycles in general, it may be said that, while for lightweights having engines up to 2¾ h.p., two-cycle engines with crankcase compression are used in 45 per cent of cases; this form of motor is not made above 3 h.p. except in isolated cases. Nevertheless, the two-stroke motorcycle engine up to 4½ h.p. has shown itself to be quite satisfactory under normal conditions of use. A machine with an engine of this type and power, having a bore and stroke of 85 x 88 m.m., was introduced at last year's show. This is the 4½-h.p. Dunelt, which has a two-stroke crankcase compression engine, three-speed gear-set and chain and belt transmission. It weighs, complete, 260 lb., and put up some excellent performances in last year's big trials.



Four semi-elliptic springs supporting A. J. S. saddle independently of frame. Springs are anchored to rear luggage carrier

The Scott is another example of a comparatively high horsepower two-cycle engine, but this has two water-cooled cylinders, 73 x 63.5 m.m. This also stood out very prominently in the big trials of 1920. But, generally speaking, the four-cycle engine is still by far the more popular system, some 80 per cent of all machines having this type of engine.

There are only isolated examples of engines with more than two cylinders. A new machine appeared at Olympia with a four-cylinder motor. This is the first British motorcycle to have a four-cylinder engine, and it is believed to be the first of any nationality of such an advanced design as to embody overhead valves and camshaft, aluminum cylinders with steel liners and certain other features hitherto only associated with car engines. The transmission of this new machine is also distinctly unusual, for from the three-speed gear-set skew gearing conveys the drive to a countershaft and thence by roller chain to the rear wheel. There is one example of a British motorcycle with a three-cylinder, radial, air-cooled motor. This also is an experimental production and did not appear at Olympia.

Number and Arrangement of Cylinders

Apart from these isolated examples, 62 per cent of British motorcycle engines have only one cylinder. Of the remaining 38 per cent with two cylinders, 25 per cent are of the horizontally opposed type. This represents a small increase in the latter from 12 months ago, and for the first time an engine maker, Coventry Victor, has a stock engine with opposed cylinders; at present it is being used only by three or four small firms with a total output of under a dozen per week. The one example of a two-cylinder opposed engine having the crankshaft longitudinally arranged has dropped out since last year, for the A. B. C. machine, which had an engine thus arranged, is not now being made, its manufacturers having closed down owing to financial difficulties. Bradshaw, the designer of the A. B. C. motorcycle and the A. B. C. (e. g., Dragon Fly) aero engines, has come out with a new horizontally opposed, two-cylinder, overhead-valve engine on novel lines. This is described separately in this report and its peculiar features are worthy of careful consideration.

Only 24 per cent of British motorcycle engines have detachable heads, and side valves are well in the majority, 68 per cent being of this type, while only 6 per cent have overhead valves and 6 per cent inlet over exhaust, the remaining 20 per cent being of the valveless, two-cycle pattern.

One well-known maker, Quadrant, has a side-valve engine with the valves set at 90 deg. from one another in the circumference of the cylinder bore. The exhaust valve is in front of the cylinder and the inlet at the side; thus the pocket of the former is equally cooled on each side, tending to prevent distortion of the seat. The inlet cam is integral with one of the timing gears which drive a lateral camshaft arranged to operate the exhaust valve.

Distribution gearing on nearly all makes is of the straight-toothed pinion type, a long train of wheels often occurring. In one case, a single-cylinder James, there are six pinions in all, but in isolated cases a roller chain is utilized.

Engine Bearings

The plain bush for crankshaft and big-end bearings is slowly being displaced by ball and roller types. The majority of recently introduced models have ball bearings for the crankshaft and roller bearings for the big ends, and, while J. A. P. engines in the larger sizes have normally plain journals, they are also supplied with a ball bearing on the pulley or chain sprocket side and a plain bearing at the other end of the shaft. The fact that this maker also favors plain bearings for the big end accounts for the fact that 61 per cent of engines are fitted with this type of connecting rod bearing. If J. A. P. were ruled out, the majority of big ends would have rollers. However, J. A. P. cannot be ignored, for, as already stated, he supplies the greatest number of stock engines. The following percentages, therefore, apply to British motorcycle engines of all sizes: Of crankshaft bearings 45 per cent are plain bushes, 36 per cent ball, 13 per cent roller, while 6 per cent of engines have ball and plain. Of big ends 61 per cent have plain bearings, 36 per cent rollers and 3 per cent balls.

Cylinder and Crankcase Construction

With the exception specified, cylinders are invariably of cast iron with circumferential radiating fins. Usually they are secured by four studs and nuts to the top of the aluminum crankcase, which is vertically divided at right angles to the crankpin axis. In one instance, the Corona, a new job with a planned output of but 500 per annum, the cast-iron cylinder and crankcase are cast as a unit, with the exception of an end plate of aluminum for the crankcase. While in four-stroke engines a pair of internal flywheels are normal with a coupling forming the crankpin, the Corona has a single outside flywheel, in which respect it resembles the two-stroke motors. One maker of a two-stroke lightweight engine machines the top of the head off flat and fits an aluminum cap with horizontal fins, securing it by a central hexagon-headed screw.

Pistons

Aluminum pistons have not secured much favor with motorcycle makers, and at the present time only 2 per cent of engines are so equipped; cast iron is, therefore, almost universal with three rings in 65 per cent and two in 35 per cent. There are several cases of the total number of rings being divided between crown and skirt. Sunbeam and Rudge engines, for example, have only one ring in the crown, the second being near the bottom of the skirt, where it serves as a scraper.

In four-cycle engines the flat-top piston with internal webbing is general, while in two-cycle motors the piston has cast with it a deflector to separate the induction and exhaust gases when both valve ports are open.

Unlike British car engines, the majority of those in motorcycles still have the wrist pin fixed in the piston bosses. There are only 19 per cent otherwise arranged, one-quarter the number of these floating in both piston and rod and the remainder being fixed in the rod.

In some cases where the wrist pin is fixed in the piston no endeavor is made to locate it except its own good fit in the piston bosses. Occasionally one end is slightly tapered, but not infrequently a parallel sided pin is used. In B. S. A. engines the wrist pin is tapered at one end to fit a taper hole in the boss; the latter has an internal groove which prevents lateral movement through the agency of a spring wire ring located in a corresponding groove around the pin.

The floating pin of Rudge engines is located by a spring wire ring in a groove at each end of the piston boss; in other cases a copper plug is driven into the bosses at each end.

Ignition.

The magneto is universal for ignition, but in the case of the Villiers stock engine, a two-stroke model with the largest output of this type and fitted to over a dozen different makes of lightweight machines, a flywheel magneto is used. This has stationary coils of large dimensions and a stationary contact breaker, all mounted on a side plate around which rotate the pole pieces within the dished flywheel; all parts including flywheel are thoroughly enclosed by a dished coverplate. An advantage of this magneto is that it has double the range of advance and retard of the ordinary type, a feature of great importance in two-stroke engines, even ignoring their comparatively high speeds of rotation.

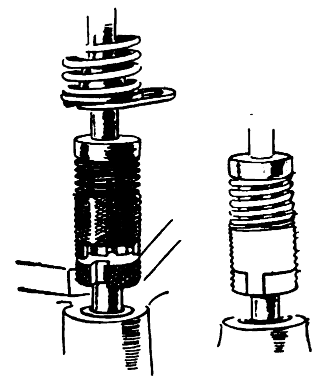
Engine Lubrication

Of engine lubrication systems there is almost endless variety, the modifications being so diversified as to prohibit any reasonable classification being made; but the purely splash system occurs in the majority of cases, the oil being delivered to the crankcase through a sight feed on the top tube, the oil being brought to this point from the tank by a semi-automatic pump. The plunger of the latter is intended to be raised or depressed by hand, a spring returning it to its normal position and delivering the oil under slight pressure to the adjustable drip feed and thence by gravity to the crankcase.

There is, however, a slight tendency toward the elimination of the separate oil tank and the carrying of the oil supply in the crankcase sump. In one or two instances, as for example, the 4½ hp. two-cylinder horizontally opposed Humber and the single cylinder Corona, the oil in the sump is delivered by a mechanically driven pump to troughs under the big-ends. But next to the simple splash the most popular arrangement is a mechanically driven pump in the crankcase, which is rotated by reduction gearing at 1/30th to 1/40th engine speed; it draws oil slowly from the bottom of the crankcase (the latter fed by drips from a top tube tank) and delivers it to the drilled crankshaft for main and big-end bearings, and thence by splash to the cylinder walls. A hand pump can be used to send charges direct to the crankcase to supplement the drip feed.

Appreciable difference is apparent in the majority of cases in the method of lubricating two-stroke engines. Until 12 months ago the prevailing method was to mix fuel and oil together in certain proportions and to rely upon the oil thus fed through the carbureter into the crankcase with the fuel on the suction stroke. But while Triumph and one or two other makers retain this system the majority now separate the oil and fuel supplies. The usual arrangement is a drip-feed delivery to the cylinder wall, the outlet having a non-return valve, and being uncovered by the piston during the upper two-thirds of its stroke and therefore delivering directly to the crankcase, the oil being drawn from the pipe by the partial vacuum occurring below the piston on its upward movement.

Finger tappet adjustment of Ariel engine. Finger plate forming valve spring anchorage is also illustrated



Levis, who may be looked upon as the originator of the two-stroke lightweight machine, has a drip feed supply to a branched pipe, one lead being taken to the cylinder wall and the other to one of the journal bearings of the crankshaft. Excess of oil from the cylinder wall drains into a gallery at the top of the crankcase and thence through an internal duct to the other crankshaft journal at the belt pulley end. The crankshaft is drilled and some of the surplus in the journals is carried by centrifugal force to the big-end.

In one case, the Precision stock engine, the main oil supply is carried in an aluminum chamber forming a side extension to the crankcase, but separate from the latter. The crankshaft projects through its journal bearing into this oil compartment and carries a chain sprocket for the magneto driving chain. The latter is enclosed and acts as a conveyor for the oil, lifting the latter into troughs whence some of it runs by gravity through an adjustable drip valve into the cylinder and so by suction to the crankcase on the up-stroke of the piston. This arrangement has the advantage of keeping all the oil in the neighborhood of the engine and introduces no extra parts, while enabling the magneto chain to be run in a bath of lubricant.

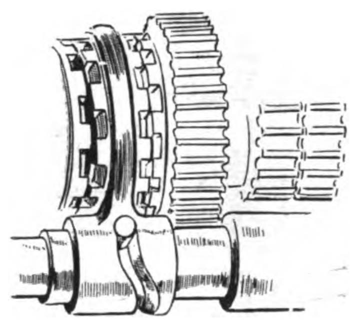
Engine Starting

The foot-operated lever ("kick starter") is almost universal where any means of engine starting other than pushing the machine is provided; Enfield is one of isolated examples having a handle, while Rudge is unique in having pedalling gear for starting the motor—not for moving the machine. Kick starters have toothed quadrants, which mesh when operated with a pinion; the latter is mounted on a quick thread and has a face ratchet drawn into engagement with a ratchet on a gear set wheel when rotation occurs.

Clutches

Ninety-five per cent of the clutches are of the plate or disk type. In those used for engines of small power, in lightweight machines, for instance, the single-driven plate pattern prevails with cork inserts, this being the type embodied in Sturmey-Archer two-speed gearsets, but with engines over 3 hp. the vast majority of clutches are of the multi-plate type, 90 per cent of these running dry with fabric friction surfaces against metal disks, the remainder being metal to metal and running in oil.

Clutch control by hand occurs in the vast majority of machines, approximately 85 per cent being so equipped, but in quite a number of instances where two-speed gearsets are used no friction clutch is provided, the gear changes from low to high being effected whilst the throttle is closed or the exhaust valve is momentarily held off of its seating by the usual lifting device. This absence of a clutch of course prevents an engine being started in neutral with the machine stationary and a gear engaged to move off; the neutral position is only utilized to wheel the machine, the engine being started by engaging the low gear and pushing or "paddling."



Forks operating dog clutches of B. S. A. gearset are moved by pins on rotary shaft working in slot of fork bosses

There is good reason for the hand control of the clutch, for with foot control the rider is at a disadvantage in not being able to move off from rest, with a solo machine, by straddling with both feet on the ground. In traffic riding especially this is an important point.

Gearsets

As already mentioned, the use of stock components is most pronounced in gearsets, 55 per cent of machines being so fitted. The majority have the gear wheels constantly in mesh, gear changing being effected by sliding dogs. The straight through change of gear shift is almost universal, there being only one example (a four-speed set) of the selector system as used on cars. Adjustable belt pulleys are used in place of gearsets by two or three prominent makers, Rudge and Zenith being the most noteworthy of these. Of the remaining machines 54 per cent have three-speeds. A great many of the lightweights can be obtained and are preferred without gearset at a reduced price. Obviously when so equipped they are suitable only for use in flat or merely undulating districts, for their hill-climbing powers are then, it need hardly be said, distinctly limited.

The unit construction of engine and gearset is not making any appreciable headway, for in 90 per cent of machines these components are separately mounted, with a primary chain drive from one to the other. An interesting combination of a unit and separate systems occurs in one instance, a lightweight termed the Metro-Tyler, which has the crankcase and gearcasing bolted up within side plates and a cradle with a top cover, which incloses the magneto midway between the engine and gearset. These three items, therefore, constitute a unit, which is mounted as such in the frame. The Wooler unit has the three-speed gearset below the crankcase of the horizontally opposed engine, the crankshaft drive to the gears being by straight cut pinions which eliminate this primary chain of the transmission; the final drive is by exposed chain.

Transmission

The most popular type of transmission for British motor cycles of all sizes is the combination of chain and belt. As already stated, the engine is in the vast majority of cases mounted separately from the gearset, and a roller chain is used to transmit the power from the crankshaft to the primary shaft of the gearset. From the latter to the rear wheel a belt is used in 48 per cent of machines, an all-chain drive occurring in 40 per cent, the remainder being all-belt. It is by no means universal practice to inclose the driving chains, in fact, while in the majority of cases the primary chain is inclosed, and lubricated by oil vapor from the crankcase breather pipe, the final chain rarely has more protection than a top shield. When chains are inclosed the casing usually consists of sheet metal, but in a few instances, B. S. A. is a good example, a cast aluminum chain case is fitted and obviously makes a much more workmanlike and permanent job. Chains are always adjustable, the primary one, as a rule, by sliding the gearbox backward or forward on its mounting; whether or not the rear chain requires adjustment, shifting the gearbox obviously necessitates some movement of the back wheel center to correspond. Douglas, in a new model with all-chain drive, rests the horizontally opposed twin engine on two longitudinal tubes and adjusts the front chain by sliding the engine backward or forward by means of a long draw bolt.

As previously inferred, the all-belt transmission is only used on 12 per cent of British machines. Usually only a single gear ratio is then provided, with a direct drive by belt from crankshaft pulley to the rear wheel; but as already mentioned Rudge and Zenith among others use as variable pulley to provide alteration of gear ratio in conjunction with an all-belt drive.

Only one British maker has adopted shaft drive, and that on a scooter, the Unibus, which has worm gearing on the back axle.

Frames

The tubular frame is practically universal. Pullin, however, as already mentioned, has a pressed steel frame, but did not show at Olympia, while in the Beardmore Precision the pressed steel fuel tank forms the top member of the frame and the steering head.

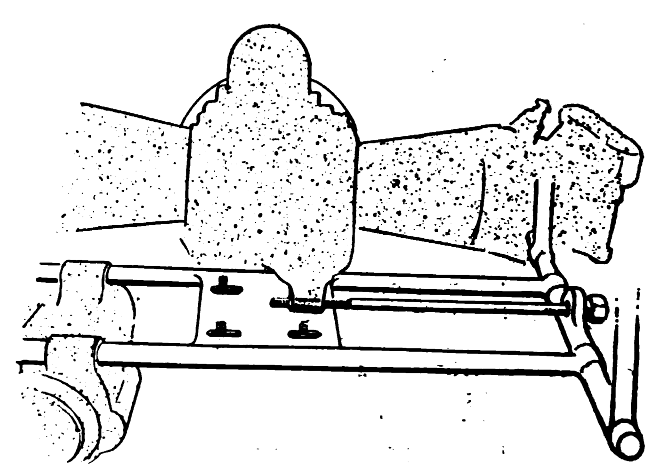


Diagram indicating mounting of Douglas horizontal twin engine in frame with draw belt adjustment for primary chain

Rear sprung frames are not increasing to any pronounced extent, 90 per cent of machines being rigid. Where the rear portion is sprung, the laminated spring is becoming increasingly popular, and there are additional examples this year of laminated sprung front forks. Most of the rear sprung frame designs are distinctly involved and costly to produce and probably the desire to keep down prices has discouraged the flexible rear suspension as more general practice.

The simplest system is the Wooler, which has its front and back axle ends mounted between pairs of coil springs and guided by slide blocks in slots in the spring cylinders.

There is no uniformity whatever in frame design, sprung or rigid. No attempt has been made to standardize this part of the machine, though one accessory maker, Brampton, has recently put forward a spring frame for assemblers, but this has been utilized by only one well-known maker up to the present.

Wheels and Tires

The use of interchangeable wheels is increasing slowly in the case of the expensive side-car machines with all-chain drive, any of the three wheels being interchangeable and carried when in position on "knock out" spindles, with a distance piece which is detachable when the spindle has been withdrawn, so that the wheel hub driving dogs or splines may be disengaged from the chain sprocket, the latter invariably remaining undisturbed when the wheel is withdrawn. A variation of this is seen on the only British four-cylinder machine, the Superb Four, which has journal ball bearings secured in the stay ends, the inner races and also the hub and chain sprocket having hexagon holes to receive the hexagon knock-out spindle.

But even where the wheels are not actually interchangeable, provision is frequently made to allow the rear wheel to be readily withdrawn, the knock-out rear spindle system being utilized for this purpose.

There is an increasing tendency to use tires of larger cross section in the heavier classes. At present the largest standard wheel and tire size is 28 x 3 in., but in the heavier tires it is probable that 3½-in tires will not be unusual in the near future. The 26-in. diameter wheel is, however, the usual size with a 2½-in. tire for medium-weight machines; for the lightweights a good many makers use 24-in. x 2¼-in. wheels and tires, though quite as many fit wheels of 26-in. diameter.

Disk wheels are not standardized, but detachable disks for wire-spoked wheels are supplied by some makers as an extra and by accessory firms. But the effect of side winds on the steering of solo machines with wheel disks does not encourage the use of the latter.

Mudguards

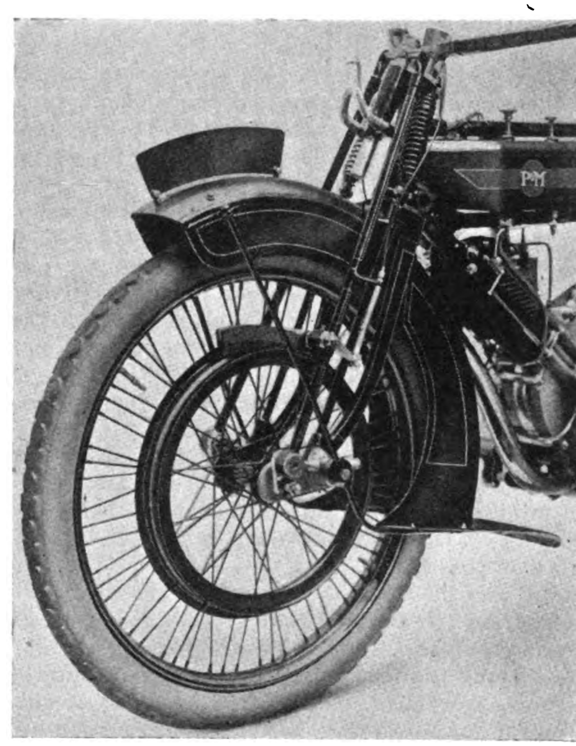
Mudguards are becoming wider, 5 to 7 in. being by no means unusual, in fact Ruby and Rover have 8-in. dome-shaped guards on the side-car model. The fitting of valances to the front is normal practice on medium-weight and heavy machines, though for rear mudguards a valance is somewhat exceptional. In place of a valance at either back or front some makers prefer flat side extensions of the curved guard.

To facilitate wheel removal and tire repair the back half of the rear mudguard is occasionally made easily detachable or, as in the case of the Rover, is hinged upon or with the rear carrier. The back end of the rear mudguard is usually supported by the stand, and in approximately 20 per cent of cases the front mudguard is similarly located, for front stands are increasing in number. Only in isolated cases is the stand pivoted round-about the center of the machine, Douglas, one of the firms with the largest output (8000 per annum) arranging a single stand in this position.

Brakes

Although it appeared probable at the 1919 show that a horseshoe brake with pads apply to the front tire rim was being rapidly discarded, it has not lost ground during the past twelve months, and 76 per cent of machines have this type of brake despite its universal condemnation by users; 18 per cent have a special V rim secured to the spokes, to which a segmental pad is applied; 4 per cent have expanding shoes and 2 per cent contracting bands, both the latter applying to drums of from 5 to 8in. diameter secured to the hub.

The prevalence of the belt transmission, with or without a primary chain, accounts for the fact that the rear belt rim is made use of for back brakes in 56 per cent of machines. Only 4 per cent of makers fail to make



P & M front wheel V rim brake, typical of many others to supersede tire rim brakes

use of this rim when a belt drive occurs. Of the remainder, 25 per cent have expanding shoes in 6 to 8-in. diameter drums, 14 per cent fit a special V rim, as in the case of the V rim front brake already referred to, and 5 per cent have contracting bands.

Only two makers concentrate the brake gear on the rear wheel, the Bat having expanding shoes within a drum attached to the hub and a contracting band on the outside of the same drum, while on the Coulson two contracting bands applying to hub drums are used.

A CABINET Conference held in Tokyo has passed the draft of the revised Japanese patent laws. The new laws, which will be immediately presented to the Imperial Diet for approval, provide for the collection of public views as to patents applied for before the applications are officially considered, the fixing of the period of cancellation of patents within five years after their being granted, the granting of patents to the actual inventors or employees inventing for their masters, and the giving of the preferential right of patent to the earlier application in case two applications are submitted for the same invention.

Poppet Valve Manufacture Requires Special Equipment

Automotive engineers will be interested in this description of poppet valve manufacture. The article discusses in detail the various operations and methods. Many special machines are used because the manufacturing problems differ from those of the ordinary machine shop.

By J. Edward Schipper

MANUFACTURE of gasoline engine poppet valves calls for some unusual equipment both because of the shape of the valve and the difficult functions which it has to perform in the engine. It has been generally found that different materials are required for the stem and head, and a great many of the valves in use are employing cast iron heads with carbon steel stems. Such a valve is manufactured by the Schlieder Mfg. Co., which specializes in this product. The capacity of the plant is 25,000 valves per day, operating on a 9-hr. per day basis.

Manufacturing this number of valves calls for the use of a great many special machines, the largest part of which have been designed in the Schlieder factory, as the problems encountered are widely different from those met in the ordinary machine shop. The factory building is a three-floor, 50 by 180-ft. structure, with a three-floor, 50 by 110-ft. wing. The main part of this building was erected in 1916, and the addition put on in 1918 to double the capacity of the plant, allowing it to reach the 25,000 per day now possible.

The valve is made up of two parts, the stem and the head. The stem stock is carbon steel, which very closely approximates the No. 1010 S. A. E. specification, the only difference being that the sulphur limit is kept lower. The heads are of very fine quality gray iron, no steel being permitted as extraordinary hardness is very undesirable.

The first operation in manufacturing the valve is to cut off the stems to a length 3/8 in. longer than is required by the finished valve. The stem stock is rolled .010 in. oversize, so that the raw stems as they leave the turret lathe shown in Fig. 1 are this much larger in diameter and 3/8 in. longer in length than the finished product to allow for future machining. The unusual feature of the turret valve used for cutting off these stems is the automatic feeder which is a special type of feeder which brings the bar up to the stop on the turret for the cut-off. The cut-off operation is simply a cross-cut.

The heads, which come as cast iron disks, are first drilled on a special six-spindle machine arranged so that the spindles are placed in a vertical line as shown in Fig. 2. This machine has a capacity of 1000 heads per hour. It is a cam-feed arrangement and the holes drilled are .010 in. smaller than the diameter of the valve stems. The purpose of this is in the welding operation, which is later described when the heads are shrunk onto the stems before they are welded.

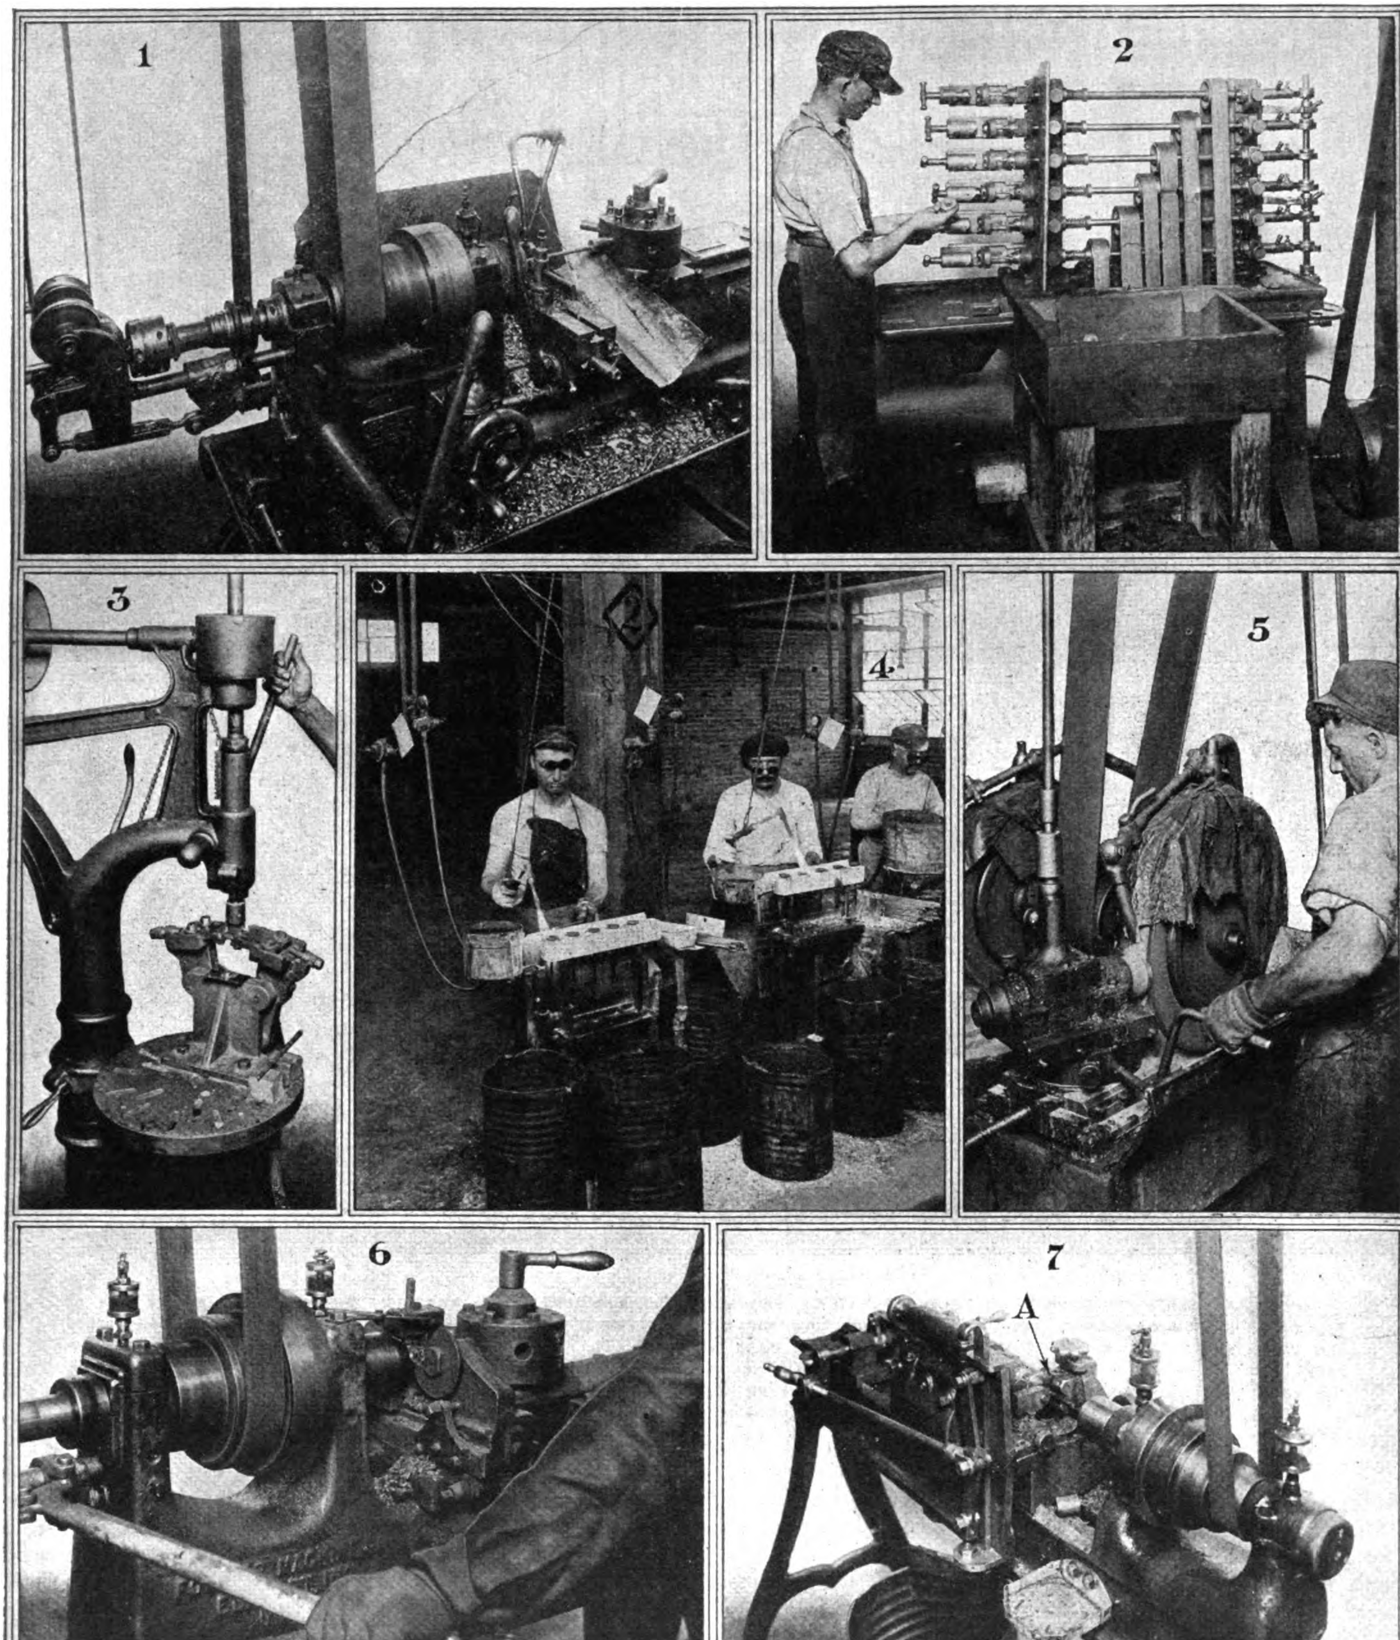
Following the drilling operation on the head, a countersink tool cleans out the countersink which is cast into the head. This operation is on a hand-fed machine with a special chuck to hold the head, and is illustrated in Fig. 3. The valves are now in position for the welding operation, which is by the oxy-acetylene process. The torch is first directed on the valve head, expanding it, and the stem is then pressed in. The stem is then welded over inside the countersunk portion of the head with a special flux which fills up the entire countersink and forms an intimate juncture between the cast-iron head and the carbon steel stem. When the carbon steel stem is forced into the head a small portion of the stem projects through, and in the welding process this is turned over and joins with the flux in filling the countersunk portion above the cup-shaped depression in the head. This not only gives a welded connection, but a sort of rivet effect, which gives a very firm juncture between the head and stem, and, in fact, makes it practically a unit part.

When the valves have been through their welding process, they are thrown into pans adjacent to the welding stand and there allowed to slowly cool. Inasmuch as these pans retain the heat from the welded valve, a sort of annealing action is provided which promotes the homogenity of the metal. The cooling in these pans is so slow that the valves cannot be handled for 24 hr.

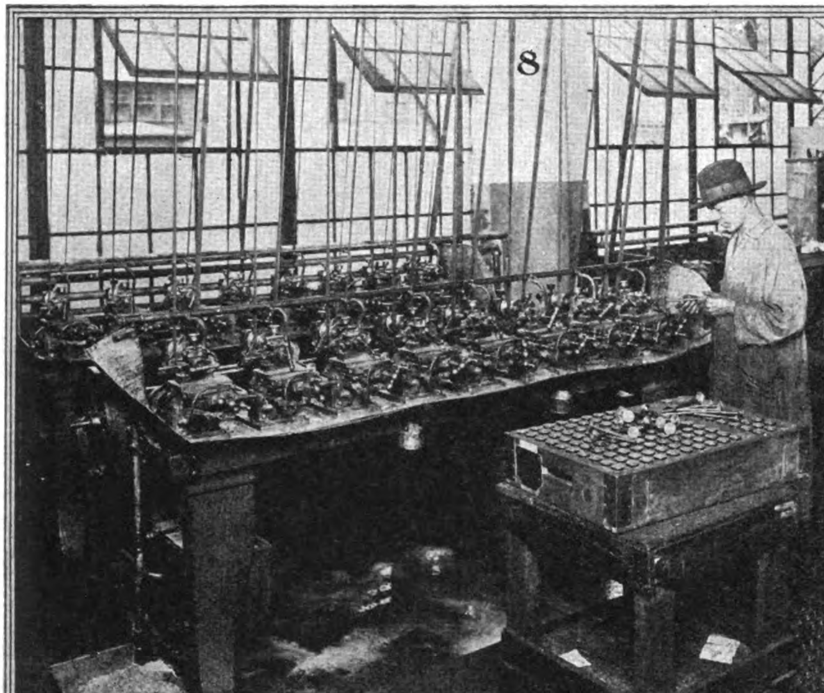
After the valves are removed from the cooling pans they are given a rough grind on the top of the valve head and the scale is ground from the bevel or seating edge of the valve. This scale is extraordinarily hard and would be very destructive to the tool if it were not removed before the machining operation. The rough grind is shown in Fig. 5.

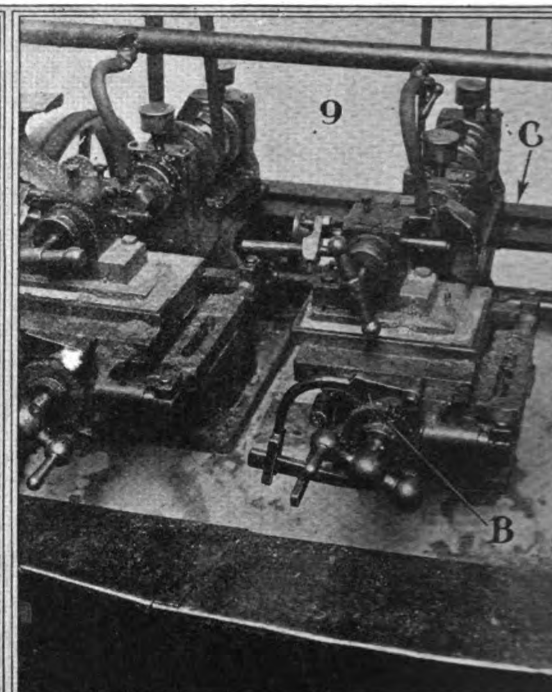
All of the work which has been done up to this point is preparatory to the machining operations. The valves are now slipped into special counting racks holding 100, 150 and 200 valves and are then passed along for the preliminary inspection. This inspector notes the weld and sees that the scale has been removed from the heads and bevel seats so that there is no danger of tool damage from this source.

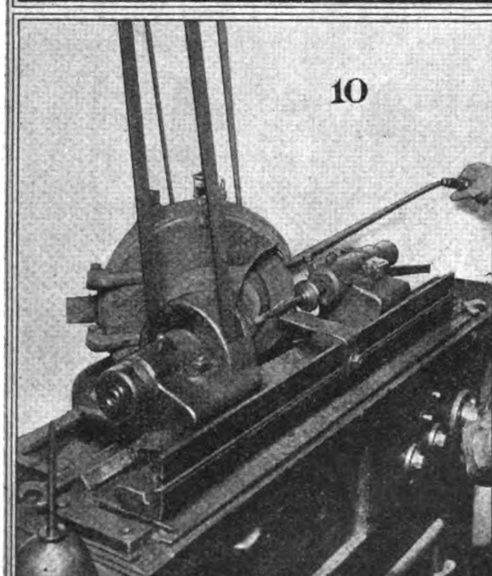
The first machine manufacturing operation on the valve is that of forming the head. This is done on a turret lathe with a compound tool. The operation is shown in Fig. 6. The machine is an ordinary Fuller turret lathe, the interesting feature being the cutter, which works on a cross-feed. This tool cuts the outside diameter of the valve, forms the seats and forms the underside of the valve to proper radii. The operation is located from the valve stem diameter, which is held in an ordinary chuck. After the head is formed in this rough forming operation, the heads are given center marks for locating the finish grinding and machining work on the stems. The centering operation, which is shown in Fig. 7, is done on a special machine, the stem being clamped in a V-block which serves as a locating means. When so clamped the

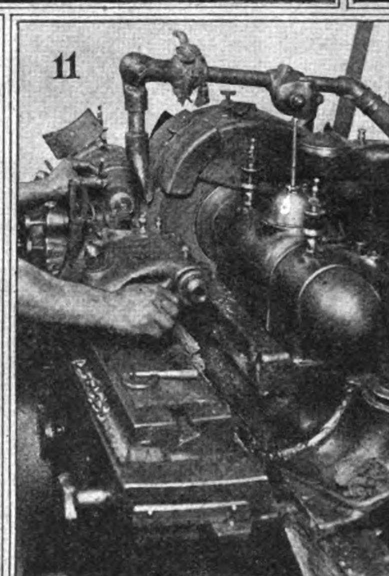


1—Cutting off stock to length ⅜ in. longer than finished valve stem. Stock is .010 in. diameter larger than finished stem. 2—Drilling the cast iron valve heads on a special machine which drills six at a time. 3—Cleaning out countersinks in the valve head casting. 4—Welding valve stems to valve head. The stem projects within the countersunk portion of the head and after welding, the projecting piece of stem and the flux when fused fill the entire countersunk portion. 5—Rough grinding the valve head to take off the hard scale after welding. 6—First machine operation which forms the head and seats of valve. 7—Operation for establishing center of valve head, locating from diameter of valve stem by means of V-block at A.









8—Eight-headed machine for slotting the stems of valves for overhead valve engines. 9—Enlarged view of one of the heads on stem slotting machine. B—Connecting rod bars for establishing reciprocating motion of heads. C—Ratchet and pawl feed for table. 10—Grinding the valve seat on a Star wheel. This grinds a 45 deg. seat on the valves, only a very light cut being taken. 11—Finish grinding the valve stem. Note the locating center point on machine. 12—Gaging the valve on final inspection. The racks contain counted valves and the inspection operation consists of a go and no-go gage on the valve stem and an amplifying gage for testing concentricity of head and stem.

center spot is accurately placed in the head of the valve.

On the overhead valves which are used in the Buick, Chevrolet and other motors, it is necessary to slot the stems of the valve, and this is done on a very ingenious machine which is capable of handling 8 stems per min. In other words, the special machine can handle as many stems per minute as it has heads. The machine illustrated in Fig. 8 is an eight-headed machine, and is, consequently, capable of slotting 8 stems per min. A close-up on one of the heads is given in Fig. 9. It will be seen that this machine, which is a product of the Schlieder company, is very highly ingenious in its operation. A crank arrangement allows the head to swing back and forth. This is the portion which carries the belt pulley. The operating bars, to give the reciprocating motion to the head, which is really a side-to-side swing, are shown behind the machine at *B*. This head carries the cutter, and the table which carries the valves is fed up to it by a ratchet and pawl arrangement, *C* which connects with a worm feed. This advances the work toward the cutter at the desired rate.

All of the valves are given either a screw-driver slot in the head or two small holes to hold the valve grinding tool, are placed in the valve on either side of the center mark. The slotting operation is done on an ordinary saw and the two pilot holes are put in by a short drill, and the valve is then ready, practically, for its finish grind.

Special valves for certain makes of cars require some additional work on the stems such as, for instance, putting a groove at the bottom of the stem, chamfering the bottom,

etc. All of the valves, before going to the grinding, are cut off at the correct length from the seat, but some of them require these special slots or key holes which take the particular type of valve spring retainers needed. In order to provide the wearing surface necessary at the bottoms of the stems, these are cyanided to give them the hard skin necessary as a wear resister.

The heads are rough ground on a Landis grinder, the same operator taking care of both the rough grind and finish grind. This is done as it is then possible to hold the operator responsible for the finished valve. It has been found where one operator took care of the rough grinding and another the finish grinding that it was impossible to locate inaccuracies. Each grinder, of course, being positively certain that it was the other one who caused the trouble. The way it is worked out now, the .010 in. oversize is ground off all by one grinder. He takes off .008 in. on the rough grind and .002 in. on the finish grind, and on a 9-hr. basis, he will be 6 hr. rough grinding and 3 hr. finish grinding.

Probably the most interesting operation in the entire manufacture of the valve is that of grinding the seat. This is done on a Star grinding wheel which takes a very light cut, the depth being just sufficient to give the desired seating surface. This wheel is illustrated in Fig. 10, and it has been selected after a long search for the proper equipment for this work. The stems are then finish ground, the excess metal which was left at the beginning on the stems being taken off on this cut. This operation, which is shown in Fig. 11, is a straight grinding operation without any exceptional problems. The valves are then checked and gaged for diameter and concentricity. The final inspecting operation is done by girls, the operation being shown in Fig. 12. On this operation the operator has two gages, an over and under go and no-go gage for the stems, and then a concentricity test which is shown in operation in the illustration. The valve is placed in a V-groove, turned about with an indicator pointer of an amplifying gage resting against it. A variation of over .002 in. is sufficient to cause rejection of the valves. Following this final inspection, the valves are flushed in oil, wrapped and packed for shipment.

German Organization of the Factory Inspection Department

THE organization of the inspection department in a machine shop engaged in the production of interchangeable parts was covered (from the German point of view) in a paper recently presented to the Dresden Section of the Verein Deutscher Ingenieure by Prof. Toussaint. In the first place there is to be created a department to which may be referred all questions relating to measurements and fits. This department should be accorded a large degree of independence, as it represents in a sense the conscience of the works and is responsible for the interchangeability of the products of the plant. The superintendent of this department should represent the firm on all standards committees that are working on the standardization of systems of measurement and fits, that concern themselves with questions relating to standard measuring or gaging temperatures and with the standardization of tools. He must conduct correspondence with the government department of weights and measures, obtain the reference gages for use in disputes concerning shop gages and see to it that these reference gages are periodically checked by the government department.

The inspection department should also work up instructions for checking measuring instruments and tools and machines. It must determine when gages are to be regarded as worn out and should therefore be withdrawn. It should furnish drawings and specifications according to which the inspectors pass tools and machines. It is charged with the proper storage and issuing of the gages, preferably in such a way that the gages for any particular job are let into a board. When the gages are turned in at the end of the week, the inspection department should be able to immediately observe any injuries they may have received and subject them to a checking process before they are handed out again.

It devolves upon the inspection department, moreover, to study the checking systems in use in the works as to their suitability and to improve upon them, to work out new inspection methods and to introduce them into service after a suitable try-out. To this end the inspection department should be furnished by the works library all publications relating to the subject of inspection and gaging.

Aside from instructions for checking the shop gages, there should be worked out general instructions regarding the use of gages in the shop. It is advisable to instruct the engineers, foremen, inspectors, assemblers and better machinists in regular courses, which results in better co-operation between drafting room, shop and inspection department. In the lectures such terms as nominal dimension, fit, tolerance, maximum dimension, minimum dimension and tolerance unit should be made plain. The location of the zero line, the influence of the gaging temperature, and the different kinds of fit should be discussed. The markings and inscriptions of the gages should be explained and shown by samples, and this should be followed by a general discussion on the system of inspection in use in the plant.

Oilless Bearings

TWO forms of oilless bushings or oilless bearings are manufactured by the Massachusetts Oilless Bearings Company. One is a bearing made of certain grades of wood impregnated with lubricant. Six different densities of lubricant are used, suiting the bearings to different conditions of load and speed. These bearings are known as phosphor lignum bearings and are used for shafts running at from 25 to 25,000 r.p.m., we are informed. These bearings are not a stock product but are made to order for any particular application. The phosphor lignum bearing is said to have a crushing strength equal to that of a babbitt bearing, to be moisture and oil-proof and not to swell or shrink under climatic conditions.

The other type of oilless bearing referred to is known as the Cole graphite matrix bearing. This is a cast metal bearing, the graphite being incorporated with the metal. The bushing comes ready to be pressed into the housing and must not be reamed or machined. In case the bearing has to be fitted to a shaft it is recommended to dress the shaft not to ream the bearing. The minimum thickness of wall is 1/8 in. and the following tolerances are worked to are medium sized bearings: Length, $\pm$ 0.010; inside diameter, $\pm$ 0.001; outside diameter, $\pm$ 0.001. These bearings too are made special for different applications, the proportion of graphite being varied.

Detailed Analysis of Holland as Market for American Automotive Products

Lack of domestic automotive manufacture renders Holland an excellent market for foreign products. The facts presented here will be of definite value to the manufacturer seeking Dutch trade. Motorcycle delivery cars are popular. There are about 10,000 automobiles in use in Holland.

By Coldwell S. Johnston*

ALTHOUGH always difficult to properly estimate the value of any foreign territory as a market, one will find the problem simplified if able to visualize the size of the country with known home districts and to know the population, its wealth and area, as well as its buying capacity and other characteristics.

Holland, or to be more correct, the Netherlands, is the smallest, with one exception, of the important countries of Europe. Its area, 12,000 square miles of land or gross total of 15,700 square miles with inland waters, is less than that of either Denmark or Switzerland, although its population of seven millions exceeds the combined population of these other two countries by several hundred thousand.

There is only one real manufacturer of automobiles in Holland, and a rich and thrifty population has to buy practically all of their motor cars from abroad.

The nearest tabulation of the number of automobiles in licensed circulation in Holland is obtained from the Royal Automobile Club, The Hague. The secretary states that the number of pleasure cars in use does not exceed 8000 or 9000; this seems too conservative, in view of the fact that 3000 cars alone from the United States were imported last year out of the gross total of 6000 from all parts of the world.

If we base our estimate on 10,000 automobiles as being in use in Holland, which is about correct, this would show only one automobile to every 700 inhabitants, as compared with one to every twelve persons in America.

At the beginning of the year 1921 there were only 20,000 motorcycles in use in this country and a steady demand for more.

The year just ended far surpassed all others as to records in number of passenger automobiles exported from U. S. A. The total is over 125,000; the first ten months of 1920 show 112,376, or double the figures of 1919, which were 67,145.

After the United Kingdom and British possessions, the Netherlands tops the list of foreign buyers with 2565 cars taken in ten months from the United States, and the Dutch East Indies with 3439, all in the ten months for which we have official figures, making a total of 6000.

Therefore, with the safe estimation of 3000 cars having been sold in Holland in 1920, of a total value of Fl. 12,612,000, or an average declared value on importation of about Fl. 4,200 per car, the important question is what are American manufacturers and exporters of automobiles going to do to increase, protect and maintain the Dutch market? (See my report published in Commerce Reports No. 306, dated December 30, 1920.)

*American Commercial Attache, American Legation, The Hague, Netherlands.

Foreign Representatives

There are in Holland the following number of automobile agents from the various foreign countries:

American	27
French	26
English	24
German	19
Italian	7
Belgian	3
Swiss	1

A questionnaire was sent recently by the Bureau to all of these agents concerning various topics of interest to the American automotive manufacturer. A digest of the replies is presented here.

Vehicles in General

But for a temporary overstock the demand for cars is good, and revival of selling in the spring will no doubt move all cars now on the dealers' floors. The attached statistics show the imports of automobiles into Holland during the year 1920 in comparison with the year 1919.

The percentage of cars in use of domestic make in Holland is negligible, there being only three manufacturers or assemblers of motor cars in Holland, so that practically all automotive vehicles in Holland are imported.

The total production in Holland of cars would not exceed, if it equals, a couple of hundred cars a year, excepting Spijker.

The Spijker plant, the most important concern producing automobiles in Holland, estimates a yearly output for 1921 of 100 cars per month, but as this car is to be a superior six-cylinder vehicle, selling for approximately Fl. 20,000, it is very doubtful now, under the financial conditions ruling, if a thousand such cars can be produced, or even half that number manufactured in Holland and sold here or abroad. The bulk of the production last year, which sold for half the price of their new model, went to England, amounting to some 350 cars of the four-cylinder model, selling to 12,000 guilders.

Passenger Cars

Holland is less affected by the depressed conditions in the European market for the sale of motor cars than any other country on the Continent, with the possible exception of Spain. Money is here and available, and

the American producers control the market to a greater extent than any other nation, although heretofore the reputation of the French car has been one of superior quality and durability.

Trucks

The ample facilities afforded by cheap waterways prevent the development of a large truck business. It is hardly worth while to attempt to force the market with anything larger than a 1½-ton truck, although some 2-ton trucks are noted in daily use.

Trucks of all types and kinds are to be seen in Holland, but the most successful and best adapted are the four-cylinder type motors from ¾- to 2-ton trucks. Exceedingly heavy trucks are rare, and, due to the narrow streets and roadways, are often impractical.

Great popularity is noted in the light delivery car and the adaption for light delivery made to attach to motorcycles for city delivery purposes.

American Advantages

The simplicity of American design and the interchangeability of parts with the quick supplying of spare parts are items that the European makers do not afford their customers. Right here the matter of service is very important and should be developed the same as at home; up to date the subject is badly neglected.

The particular type of car that might prove the best seller is naturally the one combining the lowest first cost and demonstrating its economical maintenance and operation. Europe has long been acquainted with the small-bore, high-speed motor, which has demonstrated to the satisfaction of the European that it is not an extravagant fuel user and the most economical to own.

NOTE.—*Regarding Market for Bicycle Tires:* It is remarkable to note here from the above large total of bicycle tires imported from various countries enumerated above no imports of bicycle tires were reported from the United States. The market for this article seems to have been ignored by American manufacturers and as practically everybody in Holland rides a bicycle, American makers should make an effort to obtain some of this business which can easily be had. The same applies to American bicycles, as there are none on the market here in Holland.

Total	426	396	2,128	3,042

NOTE.—*Regarding Motor Car Tires:* It is always advisable to have cars for export to Holland equipped with millimeter rims to take millimeter sized tires instead of American inch sized tires. This caution is recommended, being advisable here as well as in all other European countries.

The more closely producers aim at a car of the above type the more excellent are the chances of big business developing; to-day the ability to make prompt delivery, supply spare parts quickly and to furnish complete cars fully equipped for the road with ample road equipment are the important items in our favor.

National Preferences

No national preference is evidenced, although, as above mentioned, the French makes are favorably referred to, while a good reputation has been established by the English cars on account of their sturdy construction. The Belgian-block or stone-paved streets and roadways in Holland tend to make many American cars become noisy and develop weaknesses due to the vibration developed on stone-paved ways, where light construction results in rattles and rapid depreciation.

The reputation of German cars has suffered greatly because of the poor material and inferior finish on the post-war German cars being delivered now.

Gasoline Supply

The gasoline supply is mostly drawn from American sources, although an effort is being made to deliver from the Dutch East Indies and from the Royal Dutch Company's source of supply. Few gasoline substitutes are in the market, the most prominent being benzol. The price of gasoline, known as petrol, is 40 to 50 cents (Dutch) per liter, or approximately 60 cents (American) for a gallon.

Credit

Practically all business in Holland is done on a cash basis to the consumer, but if a practical and workable system of partial payments on motor cars were established, similar to that in effect in America, no doubt an additional amount of business would be developed and quicker sales would result.

If this was in force at the present time, it is the writer's opinion that there would be fewer cars on the agents' floors than is the condition to-day.

This system of time purchase as developed in America is not known in Holland, and there is a wide field awaiting any acceptance corporation putting it into effect.

The question of barter so often applied in Europe where the value is greatly depressed is not required in Holland.

Taxes

The Government taxation system depends almost entirely upon the income tax as a Government source of revenue. The duty on motor cars is normal and only 5 per cent ad valorem. There is a general tendency to increase the taxation, although the luxury tax has at this writing been practically abandoned or delayed for the present, so that it will probably not become a handicap in the immediate future for the importation of motor cars.

No special taxation on foreign companies is levied, and foreign companies have the same rights as native. If located in Holland they are obliged to pay the income tax estimated on the business done in the country. (See my special report on this subject: Incorporation, Branches and Taxation on Companies, Foreign and Domestic, in Holland, dated November 3, 1920.)

Tax on Motor Vehicles

There is no tax on the following vehicles: Automobiles held by public authorities; equipped as ambulances; trucks; those used by manufacturers and dealers in carrying out their business.

All other motor vehicles (excepting motorcycles) are taxed according to value as follows (the selling price of the car is considered as the value):

Less than Fl. 2,000; Fl. 2 for each Fl. 100.

Fl. 2,000 or more, but less than Fl. 4,000; Fl. 40, plus Fl. 2.25, for every Fl. 100 over Fl. 2,000.

Fl. 4,000 or more, but less than Fl. 7,000; Fl. 85, plus Fl. 2.50, for every Fl. 100 over Fl. 4,000.

Fl. 7,000 or more, but less than Fl. 10,000; Fl. 160, plus Fl. 2.75, for every Fl. 100 over Fl. 7,000.

Fl. 10,000 or more; Fl. 242.50, plus Fl. 3, for every Fl. 100 over Fl. 10,000.

Three-wheeled motor vehicles, each, Fl. 15.

When used exclusively for business purposes, the tax is decreased one-half of the above amounts; when used principally for hiring by taxi company or by dealers or manufacturers of motor cars, the tax is decreased to one-quarter of the above amount.

The import duty into Holland on motor vehicles is 5 per cent ad valorem.

The taxation system on motor cars seems to be in a chaotic condition at the present time, 1918 taxes having not been collected as yet.

Agriculture

Holland is primarily an agricultural and dairy farming country; the average farm is about ten acres. There is approximately 1,210,000 hectares (2½ acres 1 hectare) of permanent pasture land and 867,274 hectares under farm crops. Every square foot of available land capable of cultivation has long been carefully utilized by the industrious Dutch farmer.

Live stock is showing a large increase since the armistice and has now approximately reached its pre-war figure, or about 2,400,000 cattle.

Farm labor seems adequate, although there is a tendency on the part of the Dutch farmer to emigrate to America. The farmer is better off than in 1914, having never received such high prices before, and is still maintaining a good price for his products.

There is no rapid increase in the use of farm machinery except where the falling off in labor supply has introduced the installation of some few motor implements. Tractors have not been used to any extent. Because of the low lands in Holland only light tractors can be used, nothing heavier than a Fordson or Samson being practicable.

Transportation

Shipping is adequate; the best ports are Rotterdam and Amsterdam. The first named has direct steamer connection with America, and there are ample facilities for storage for all kinds of goods; free port facilities for goods stored entreport for shipment to other countries can be had at Rotterdam without paying customs duty on goods to be re-exported.

Railroads are equipped to handle shipments direct from warehouses to any European country where reasonably normal conditions exist. The canals, however, play the greatest part in the transportation of freight in the Netherlands.

IN Munich, Germany, hearse service has been "communalized" and will be carried out by means of gasoline automobiles exclusively in the future. Heretofore the service has been partly in the hands of livery men, who furnished horse-drawn hearses, and partly of the city, which owned a number of electric hearses. The change from electric to gasoline hearses was due to the fact that the electrics were about worn out.

Exports of Automobiles and Tires for April, 1921.

The FORUM

Steam Cooling

Editor, AUTOMOTIVE INDUSTRIES:

Referring to the interesting article on Mr. Rushmore's cooling system described in AUTOMOTIVE INDUSTRIES of May 26, the writer wishes to mention that early in 1918 he designed a cooling system based on the same principle, which, however, showed a somewhat different mechanical arrangement, as will be seen from the following brief description.

A conventional radiator is modified in such manner that the steam entering from the motor has to follow a certain predetermined path through the entire cooling portion, the water being collected in the bottom tank, from where it is returned by a positive pump in such manner that syphoning back owing to leakage of the pump is impossible.

A water supply tank is provided for the purpose of keeping the water in the motor at a predetermined height in case of loss through leakage or failure of the radiator to condense all steam under extremely unfavorable working conditions.

An adjustable blow-off valve may be provided permitting variation of the temperature, and if located at the outlet of the motor, relieves radiator and hose connections of the pressure against which, however, the pump has to lift the water in this case.

The advantages of this cooling system in comparison with the one developed by Mr. Rushmore are the following ones:

(1) Quicker heating and more uniform temperature of the motor owing to the absence of water circulation at any time.

(2) Assurance that at all times, especially when starting, the jacket is filled with water, which according to the sketch showing the application of Mr. Rushmore's system to a Cadillac car does not seem to be assured.

(3) A still smaller pump can be installed because its capacity has to be sufficient only for returning the maximum quantity of water evaporated by the motor plus a factor of safety, while in Mr. Rushmore's system the pump has to be large enough to fill in short time the jacket which will be empty if the water level in the tank stands below the outlet pipe from the motor.

There is no doubt that cooling by evaporation is one of the most important steps toward increasing the economy of motor vehicles, but in many cases the design of the motor will have to be adapted to the working conditions at a higher average temperature.

Anent the subject of economy, it might be mentioned that previous to working on the cooling system the writer designed a device described below for assuring a dry charge of, as far as possible, uniform temperature, which in connection with the evaporation principle of cooling should materially increase the fuel economy of the conventional motor vehicle engine besides reducing crank case dilution.

To the exhaust manifold of the motor is attached a stove of extra large heating capacity from which hot air is conveyed to the main and auxiliary air inlet of the carbureter; the charge leaving the carbureter passes a thermostat which expands as soon as the temperature of the charge exceeds a predetermined maximum insuring the absence of liquid fuel particles; this expansion opens a valve provided in the hot air line to the carbureter which admits cold air, thereby causing the temperature of the charge to drop.

Preliminary experiments with this latter device gave promising results, but war conditions prevented further development, while the cooling system, for the same reason, did not reach the experimental stage; later on the writer did not have any opportunity for further experiments.

VICTOR JAKOB.

How Trucks Can Be Improved

Editor, AUTOMOTIVE INDUSTRIES:

In reply to your letter of April 27, containing the question, "What do you regard as the next step in truck design to render them more economical and more satisfactory in the hands of the user?"

I am pleased to submit a short discussion on some of the phases of truck development yet to be achieved.

Barring certain engine modifications which may or may not come about as the result of research activity in fuels, it is not stating too much to say that the engine design of trucks has reached a point where the fundamentals are shaken down to a basis of general understanding. We understand the power requirements and the methods of application. We understand the speed requirements and limitations. We are manufacturing trucks of a very high degree of interchangeability of parts, and we are constructing vehicles of great reliability and economy of operation.

To my way of thinking, the next step in truck design is to make them more suited to the requirements of operation and maintenance, and we must improve the design to a point where the parts are easily accessible for repairs, and we must provide cheaper replacement parts in the way of bushings, sleeves and pins at all wearing places, in order to facilitate saving in time and expense in making repairs. This will do away with the replacement of large parts of the vehicle, which are often scrapped, due to the fact that while 95 per cent of the part performs a non-wearing service, the other 5 per cent is subject to wear, and replacement of the entire piece is necessary.

More study is required in reducing the points of lubrication, and facilitating the none too pleasant operation of oiling and greasing of the vehicle.

It is generally recognized that the driver must have reasonable comfort and protection, in order to accomplish the best results. This point is worthy of still further study, as it pays a handsome return on the investment.

In increasing the power and road ability of trucks, it is necessary also to increase the braking ability or stopping ability of motor trucks. It is not only necessary to have enough braking ability to slip the wheels under any conditions, but it is necessary to so arrange the system as to dissipate the enormous amount of energy liberated in the operation of braking. This is particularly true in hilly sections of the country. It calls for a separation of the

braking systems, and the front wheel brakes loom up as a possibility.

The only remaining point has nothing to do with truck design. However, it has everything to do with truck operation in certain lines of work, viz., the development of auxiliary power devices to be used in conjunction with motor trucks. This is an ever widening field, and there is bound to be great development in the years to come.

THE PIERCE-ARROW MOTOR CAR COMPANY,
Francis W. Davis, Consulting Engineer,
Truck Department.

Thermostats in Extremely Cold Weather

Editor, AUTOMOTIVE INDUSTRIES:

In reading Mr. Heldt's article on the cooling system advised by Mr. Rushmore, the writer was somewhat surprised at a statement made to the effect that it is the practice of manufacturers of cars using thermostats to suggest that they be thrown out of operation during very cold weather.

So far as the writer knows, the Cadillac Company was the first company to adopt thermostatic control of the cooling. This company has never recommended that the thermostats be thrown out of operation during cold weather or at any other time, for that matter, except when the cooling system is being filled or drained.

Since the thermostats open the control valves when a predetermined temperature is reached, regardless of the temperature of the atmosphere, there is no reason, in the Cadillac construction at least, why the thermostats should be thrown out of operation.

The writer believes that Mr. Heldt was in error and that this statement should not stand uncorrected.

CADILLAC MOTOR CAR COMPANY,
E. C. Garland, Technical Department.

We were given to understand by our informant that the reason for cutting out the thermostat in extremely cold weather was as follows: If a driver is in a hurry and starts out with his car in zero weather before the thermostatic valve has opened, with the water stationary in the radiator core and the very cold air being forced through it by the motion of the car and drawn through by the fan, it takes but a very short time till the radiator core is frozen solid. This would prevent all circulation when the thermostatic valve opened and might result in serious damage. The fault, of course, would be with the driver, who should know that under such conditions it is not safe to start out before the engine has become warmed up and the thermostat has opened.—ED.

The Next Step in Tractor Design

Editor, AUTOMOTIVE INDUSTRIES:

We believe that there is a real need for a two-plow tractor of such a design as to be a satisfactory unit for drawbar work and belt power, as well as for cultivating. We believe that it is possible to design a machine of this size which will accomplish these three classes of work in a satisfactory manner. In our opinion, it should be a three-speed tractor, with possibly two belt speeds for the different classes of belt work which must be done.

In order to enable this tractor to successfully cultivate or harvest certain row crops, such as potatoes, sugar beets, etc., it would seem necessary that the wheels be adjustable laterally. It should also be possible to couple readily and properly to binders, mowers and similar harvesting machinery, and to belt conveniently to all forms of belt-driven farm machinery. It should be, as nearly as possible, a universal power unit for the small farm, designed to use existing types of farm machinery wherever possible and to eliminate animal power as much as possible.

In our opinion, the design of three- or four-plow tractors should be dictated mainly by the drawbar and belt work which they must perform. More attention should be given to refined design, better materials and more careful workmanship. These same remarks apply to the large tractors used on large grain farms, particularly, and for road-building work.

The track-laying type of tractor must be considered from a different viewpoint, as it is a machine intended to operate under different conditions than a wheel machine is expected to do.

Yours truly,
MINNEAPOLIS STEEL & MACHINERY CO.,
A. W. Scarratt, Automotive Engineer.

Non-Ferrous and Organic Materials

IN connection with aircraft development during the war a great deal of experimental and research work on materials of construction was conducted, and most of the results obtained found their way into the publications of the national advisory committees on aeronautics of Great Britain, the United States and other countries. Aircraft construction makes use of a great variety of materials which while extensively used in other lines previously, had never had to meet such rigid requirements of strength and lightness. These different materials with the exception of steel are dealt with in a book by Arthur W. Judge published by Sir Isaac Pitman & Sons, Ltd. It bears the title of Non-Ferrous and Organic Materials and is the second volume of a set on Aircraft and Automobile Materials of Construction, the first volume of which relates to steels.

The second volume, here under review, covers a great variety of subjects, as follows: Aluminum and its alloys; Copper and its alloys; Bearing metals; Nickel and its alloys; Structure and properties of timber; Testing of timber; Airplane fabrics and coverings; Dopes and varnishes; Glues and gluing; Rubber and its compounds; Paints and painting; Miscellaneous metals and materials; Veneers and plywoods; X-ray method of examining materials. Owing to the great variety of subjects covered they are dealt with in a rather superficial way and the book is generally of an elementary character. It is obvious from the above outline of the subjects covered that aircraft materials are given first consideration, but as most of the metals dealt with are used also in automobile construction their applications in that field are referred to. For instance, in the chapter on Aluminum and its Alloys there are illustrations of cylinder castings, aluminum pistons, a dashboard, etc. Numerous references to sources where more complete information can be found are given throughout the volume.

ACCORDING to a report recently issued by the Dutch Department of Commerce there was a heavy increase in the imports of automobiles and tires into Java and Maduras in 1920 over 1919. There were imported in 1920 1372 motor trucks (621 in 1919), 4448 passenger cars (2470) and 247,663 tires (200,936).

Strength of Labor Lies in Definite Objective of Organization

Employees never forget their text and seldom do they wander far from it, but the employers usually organize for a merely defensive purpose and their objective wanders from meeting to meeting, consequently they never reach a goal. What is written here has many applications.

By Harry Tipper

I HAD a visit from a gentleman the other day who is getting up a new organization of an industrial character. His purpose in visiting me was to find out if I could attend the organizing meeting to suggest to these gentlemen how they can organize. The comment which he made in the course of conversation was very interesting. After visiting one or two associations, he said, "Most of these organizations do not seem to know where they are going. They have no definite object."

May and June are convention months in the business world, and I have had ample opportunity to find out the correctness of this statement.

I have just returned from a convention of approximately two thousand people representing an organization of nearly twenty-four thousand. Among the men who are interested in the development of this organization I heard very little which would indicate that they were moving in a definite direction or had a definite object in front of them.

We have in this country a very large number of business associations and we seem to be confused by the volume of activity in these associations. The volume of activity is not important. The tendency of the movement is important because the movement grows in intensity, not by virtue of the volume of its activity, but by virtue of the definition of its objects.

The power of the trade union to discipline its members, to preserve its characteristics and to influence outsiders is due primarily to the careful definition of its objects. For years the trade union has been moving in a definite direction with a very definite object in front of it.

Even in countries where the trade union itself represents only a small proportion of the working population, the influence of its movement is to be observed in all the discussions upon labor, industrial conditions and the general industrial economics. Even those reactionaries who have refused to see any value in the collective organization of workers have been obliged to take new positions every few years from the pressure of public influence and their own readjustment to outside conditions. Similarly, the definition of the Socialist creed has exerted an influence upon the modern political thinking far beyond the confines of the organization itself and far beyond the liberal elements in the population.

In comparison with these movements the organizations of manufacturers and other employers have developed a great amount of activity with little or no definition of their objects. They have exerted little influence outside of their own membership, and their actions have not affected the political or social thinking to any considerable degree.

Most of these organizations have been started without any definite object other than the protection of the members against the aggression of outsiders. This is the negative and defensive attitude, and these organizations have been obliged to modify their policies, rearrange their objects to meet the new attacks coming from different sources. Taken all in all, the business and professional associations in the United States comprise a membership much larger than the membership of the American Federation of Labor, but as far as their influence is concerned they have no definite common object of any kind, they are moving in no particular direction and their movement does not intensify particularly even after a number of years of action.

The same situation is developing in the discussion of industrial relations. All groups of labor, where they are affiliated with the American Federation of Labor or grouped within the establishment, have two or three definite objects in common. As a rule they do not know how these objects can be obtained most effectively, and they are not in any position to offer a suggested solution of the present problem.

They have indicated the objects, however, and they have suggested the solution they believe to be correct. Because of this definition they have convinced a large part of the working population that the objects are more or less reasonable and the solution more or less valuable.

Professional and industrial associations dealing with the human side are new. They should offer opportunities for the better definition of the human problems of industry and the suggestion of better methods looking to solution.

At present, however, they are floundering around after the manner of so many other associations endeavoring to secure a great volume of activity, discussing and considering matters covering a wide range, and with neither a definite object in front nor a continuing policy of development.

It is interesting to note that it was comparatively easy to secure a unity for the negative object of protection against the aggressions of Germany. That situation produced a larger measure of unity in action and in thought than any other situation since the beginning of the mechanical civilization.

For the positive purpose of peace, however, and reconstruction, we have been unable to preserve even

a decent measure of unity in respect of the most important objects.

An enormous amount of time has been expended in dickering over this or that detail of the matter without success. It is not at all sure that we have elements of peace in the agreements that have been made so far. The same thing is true of the small nations created by the war. They have been a unit in demanding recognition and protection of their racial traditions and associations. That accomplished, they have fallen into the usual political disturbances in attempting a reconstruction program.

It is the same way in business. Men will get together for protection against legislation, for protection against labor troubles, for protection against poor creditors, but in the attempt to throw up a positive program of improvement they fall apart, either becoming negative or split into other associations. It is to be expected that the labor unions of Great Britain, now that they are approaching the responsibility of constructive necessities on account of their great power, will find it impossible to secure the adherence of the millions of workers to any program of construction. The reason for this impossibility of agreement upon constructive measures is obvious. Only a very small percentage of the leaders have definitely examined the situation sufficiently far to build up a program of improvement, and the rest of the population has not even thought beyond the deficiencies.

The improvement can be made, then, only because of the activity and the intensity of the movement of the small minority of any association. **This minority must be prepared to lay down a program within the range of practical possibility to compromise on some of their objects in order to secure a movement in the right direction and to continually force upon the majority the necessity for this development.** They are not liked by associations and they are frequently discredited by the majority who do not understand them. Many of the great English leaders who brought the labor party to its present power died discredited by their own party.

Manufacturers who have been bold enough to experiment in the endeavor to provide a better basis for the co-operation of labor and management are looked upon as fools or denounced as Bolsheviks.

Not much can be expected from the organized associations dealing with the human side of industry; improvements must come from the patience and experimentation undertaken by men who have studied the situation sufficiently to know that they are right, and who are not very careful to receive the plaudits of the general body.

Reinforced Concrete Roads in France

THE use of reinforced concrete as a road material has made its appearance in France and has been experimented with in the city of Lyons with good results.

This invention is the property of the Pont-a-Mousson Steel Works, one of the biggest firms in France specializing in iron pipes. A concrete foundation, varying in depth from 4 to 8 inches, according to the amount of traffic to be carried, is first laid and given a surface dressing of fine cement about half an inch in thickness. Before this is quite dry it receives the cast iron reinforcement, the elements of which are roughly square frames 1¾ in. in height with a spur from each corner, and are laid staggered, from 16 to 25 to the square yard, according to the amount of traffic intended to be carried. The base of each cast iron member is slightly reinforced in order to give it a better seating in the cement. Finally a layer of concrete composed of fine Portland cement and quartz chips is laid over the metal reinforcement and carefully tamped down so as not to disturb the elements. When finished the metal is hidden, the road having the appearance of an ordinary concrete highway.

According to the report issued by the road engineer of the city of Lyons, after the road had been in service for six months, during which time it had carried exceptionally heavy traffic, the results are satisfactory. It is stated that the metal reinforcement now slightly projects, but not sufficiently to cause any inconvenience to traffic, and so slightly that for all practical purposes the surface can be considered as perfectly smooth. Water flows off easily and the street is less dusty than others paved with granite blocks.

The cost of construction of this experimental road was $5.30 per square metre (nominal exchange), but this was higher than normal, owing to the total inexperience of the workers in this class of road construction. It is estimated that with a little experience cost would be reduced to $5 per square metre, or even less.

Other experiments have been carried out in towns in the east of France, where reinforced concrete roads have been in use for nine years. It is found that with the correct mixture of surface dressing there is only a very slight tendency, and after a long period, for the cast iron members to project above the surrounding surface, and even when considerable wear has taken place there is no inconvenience to vehicular traffic.

The cost of construction on a pre-war basis is given by the Pont-a-Mousson Steel Works as $3.80 per square metre for their reinforced concrete road, compared with $4.45 for asphalt, $4.46 for wood blocks, $4.77 for granite blocks on sand, and $5.32 for granite blocks on concrete. One of the main advantages claimed for the reinforced concrete road is that maintainance costs are practically nil, whereas wood paving blocks cost as high as 42 cents per square metre per annum.

Management's Responsibility to the Salesman

A NUMBER of sales managers were asked this question recently by St. Elmo Lewis: "What one thing can the salesman do to overcome the present sales resistance?" Many of the answers were interesting, but that given by F. M. Manning, director of sales, Diamond Match Company, bears an especially pertinent message to the manufacturer at this time. He said:

"I would like to throw this thought into your question: 'What is the house doing to make it possible for good individual sales effort to accomplish results?'

"Too many of us unconsciously regard the salesman as the creator, gatherer and finder of our business. . . . And when we need more business we usually start to 'stimulate' the salesman.

"We owe the salesman a product, a price and a proposition which will be successful if the salesman presents it properly to the prospect. I think there is a tendency to under-estimate the responsibility of the management and to over-estimate the responsibility of the salesman.

"Therefore, we should ask ourselves the question, 'What are we doing to make it possible for the salesman to overcome the present sales resistance?'"

This attitude on the part of the management will produce results. The problem is not to find reasons for lack of sales, but to find ways of making sales. "Passing the buck" may excuse the individual, but it will not sell cars and trucks.

The recent trend of prices and production methods indicate that the automobile manufacturer has realized his share of the responsibility and that he is facing the issue squarely.

We Have the Power

THE recent reports of the Bureau of Census have established the automotive industry clearly as ranking second in value of a finished product.

This classification is interesting, especially so in that it supplies a key as to the position the industry should take in the business world. The industry is new and it has been the victim of many and varied opinions within its own ranks. But there is nothing like a touch of adversity to bring people together. A man and wife may fight each other, but in nine cases out of ten when the outsider attempts to take part in the fight, both will turn on him.

During the last winter many differences of opinion were buried under snow drifts. The industry is reaching a common viewpoint as to what is good for it. Just now there are several points of general interest before the public, especially the political public and each member of the industry should use his own political power to promote the best interests of his own industry. Each member of the industry has political power, and so has his wife. Among the ideas that need promotion are:

The Townsend bill that has been reported favorably by the Senate.

A reasonable tax law by Congress.

A drastic curtailment of Federal expenses.

A just recognition of business by Government.

Legislators and other government officials are merely human, after all. They frequently will move in the line of least resistance. Many industries are better organized for promotion of self interest that the automotive industry and, consequently, get more recognition. We believe the position taken by the automotive industry on these public questions has been the position for the greatest good to the greatest number, and each member of the industry should do all in his power to promote the common platform.

An Inventory As a Liability

IN a recent speech before a gathering of business paper editors George M. Graham asked permission to tell a short story, illustrating a point about inventories, before he began his real talk of the evening. His story was, in effect, as follows:

"This morning I arrived in New York at 9 o'clock

wearing a straw hat and found that it was raining. The rain continued to fall all day and as I moved about the city making calls, I employed taxicabs, primarily to protect that straw hat. When I had finished the day, I found that if I had started the day by throwing that straw hat under a truck and had bought a cap I would have been several dollars ahead. I am suggesting this, merely to present the view that sometimes an inventory can be a liability instead of an asset."

It would be interesting to know how many automotive concerns have made the inventory of a year ago a liability by protecting it with high sales prices.

Motorcycle Activities Abroad

ALL of the European countries which participated in the war are more or less impoverished, and, to judge by current exchange rates, the European neutrals are in a not much better position. This condition is being reflected by the demand for motor vehicles in the different countries. There is great need for motor transportation by reason of the inadequate railway services, due to different causes. The war, with its intensive industrial activity, brought home the advantages of quick travel, and the only thing that stands in the way of heavy motor car sales in Europe is the economic situation.

Speaking in general terms, Europe wants the quick transportation which the motor vehicle makes possible, but cannot afford the expense which generally goes with the touring type of car, the sport runabout or speedster. It is, therefore, natural that it should turn to the most economical type of motor vehicle known, the motorcycle. There has been a greatly stimulated interest in motorcycles in all the large European countries since the war, most of all, perhaps, in Germany. Motor vehicles are increasingly used for business purposes, and in practical work it is seldom that more than one or two persons need to be carried at a time. The motorcycle with side car provides transportation for up to three persons, and therefore meets the practical requirements of a great many people. Its economy is the result of its low weight and relatively simple construction.

In Germany the development has run to a certain extent in the direction of fitting ordinary pedal cycles with gasoline engines and driving means. It is hardly necessary to point out that this line gives very little promise of success, because a framework and wheels designed for the restricted weight and power of the rider quickly goes to pieces when subjected to the additional weight and power of a mechanical engine. The conversion plan, of course, appeals to the man who owns a bicycle, since the outlay required is very much less than that for a new motorcycle. But it is not very likely that the popularity of converted pedal bicycles will outlive the reconstruction period.

There is evidence of much thoughtful development work being done on motorcycles throughout Europe. The pressed steel frame, for instance, has made its appearance in a number of rather attractive and promising designs. By the use of pressed steel the designers may succeed in solving the problem of protecting the rider from mud and dust. Spring suspension is also receiving much attention, and this may result in a material increase in riding comfort. A large market for motorcycles in Europe is practically assured for the next several years, and technical developments will undoubtedly be commensurate with commercial activity.

A Notable Victory for the Straight Side Tire.

OWING to the fact that there is a large international trade in automobile tires and that tire renewals must be provided for cars extending through a number of countries, it is hardly conceivable that the present double standard of tire design will be maintained; that is, that both the straight side and the clincher tire will continue to be made in all sizes. The recent agitation against the straight side tire in France has brought the matter to a head, and it seems that there will be from now on persistent rivalry for supremacy. In contrast to the leading French tire manufacturer, a number of the smaller French makers have taken a favorable attitude toward the straight side tire, and one or two have even decided to manufacture it.

The greatest accession of strength to the ranks of the straight side protagonists, however, has been that of the Dunlop Rubber Co. of Great Britain, which has reached the conclusion that the straight side tire has a balance of advantages over the clincher type, especially in the larger sizes, and its chief product hereafter will be straight side, cord passenger car tires. The conversion of the Dunlop company to the straight side principle for automobile tires is particularly significant, because the design of the straight side tire is based on that of the Dunlop type of bicycle tire.

Little Manifold Heating in Europe

EUROPEAN engineers have not gone nearly so far as we have in the matter of applying heat to the incoming charge, as is evident from the article on manifolds by Messrs. Bradley and Gerster in this issue and from descriptions of European cars that have recently reached us. This may be in part accounted for by the fact that none of the large European industrial countries has the low winter temperatures that we have to contend with, but the chief reason undoubtedly is that the gasoline sold in Europe at the present time does not have the low end point that ours has. As compared with the United States, the number of automobiles in use in the different European states is comparatively small, and the demand for gasoline there does not bear the same proportion to the demand for other petroleum products that it does here, hence there is not the same temptation to convert as much as possible of the crude into gasoline. As a result, European engineers are now using about the same vaporizing and distributing devices that we used about two years ago.

June Sales Prove Gloom Untimely

New York Business Far Ahead of May

Price Reductions Start Rally Which Is Continuing Strong —Registrations Swamped

NEW YORK, June 18—Spurred by price reductions which seem to have convinced at least part of the public that automobile prices have at last been stabilized and by ideal June weather, passenger car sales in the Metropolitan territory since June 1 have run far ahead of May business, which in turn was 727 cars ahead of April.

Actual figures on June sales will not be available until the end of the month, owing to lack of daily compilation of figures in the Motor Vehicle Department, but reports from Albany show that there has been a veritable avalanche of registrations.

May registrations for ten counties in and around New York, just compiled, show a gain of 727 over April. This in itself is an illuminating commentary on the effect of substantial reductions. April had been a big month, for April, sales having been stimulated by the early spring. May started off poorly and indications at the end of two weeks were that the April total would not be reached. However, following the lead of Marmon and Jordan, price reductions followed each other rapidly throughout the month and by the fifteenth sales were running far ahead of the daily record of April and the final report showed that the last half of May had splendidly offset the slump of the first two weeks when two or three price reductions not immediately followed by manufacturers generally left the public in a state of confusion wherein purchasing was scant.

All Classes Find Buyers

An interesting study of passenger car registrations, which are equivalent to deliveries, is made possible through information contained in the Automobile Sales Analysis published monthly by Sherlock & Arnold and patronized by most of the metropolitan dealers. According to this report, registrations in ten counties in and around New York for the first five months of the year were as follows:

	$3000 and Up	Under $3000	Total
January	101	470	571
February	185	1383	1568
March	385	2919	3304
April	561	4749	5310
May	579	5458	6037

ALL COMPANIES SHARE IN HARVEST OF SALES

NEW YORK, June 21—Retail sales of automobiles in all sections of the country promise to surpass this month the record set for April and the volume of business will be materially greater than in May. The greatest sales harvest is being enjoyed by the companies which have made substantial price cuts, but it is reflected all along the line, and companies which have not made reductions are sharing.

Reports on sales conditions, gathered by correspondents of AUTOMOTIVE INDUSTRIES in distribution centers, all show that almost without exception June business is running ahead of the last two months. This seems to be true particularly in the New York and Chicago territories.

Manufacturers who were deeply pessimistic at the end of May now admit that the outlook is brighter and a considerable number declare that the orders on hand will carry their plants through the middle of July on the present production schedule.

The Goodyear Tire & Rubber Co., which announced a short time ago that the automotive industry was due for another slump and prepared many of its employees for a lay-off, has been compelled to recast its plans. There will be no curtailment of production, and there will be no extended vacation for "inventory."

The outlook, as forecast in AUTOMOTIVE INDUSTRIES of last week, is distinctly encouraging. Sales probably will slow up in July and August, but there is every reason to believe there will be a renewal of interest and a resumption of buying with the coming of September.

Detroit Sales Jump

DETROIT, June 18—Dealers handling cars on which prices have been cut, report increases in business in the last 10 days ranging from 100 per cent to 1500 per cent. On the other hand, dealers handling cars on which no cuts have been announced are not having this increase. G. O. Simons, Overland and Knight distributor, reports an increase of 200 per cent. T. J. Doyle, Dodge, reports an increase of 1500 per cent.

Best Month of Year in Chicago Opinion

Price Cut Lines Lead in Demand But All Dealers Get Share— General Outlook Good

CHICAGO, June 18—Automobile dealers in this city are almost a unit in declaring that business for June is better than for April or May. Naturally the largest business is being done by those lines which have made substantial price cuts but conditions are by no means discouraging even for dealers whose companies are standing pat on prices. Collections are good and most dealers are satisfied with the outlook for the future although they expect that there will be the usual slump in sales the last half of July and August.

Oakland sales in May were the largest in seven years, showing an increase of 175 per cent over April and the indications are that June will be as good as May. Prospects are numerous and the outlook is bright.

June sales of Oldsmobile are not as good as in April or May but the volume of business thus far in 1921 has been better than in 1920 up to June.

Overland reports a 500 per cent sales increase over April and May and already has delivered as many cars this month as in any previous month. Cash is being paid for many of the cars.

June business for Franklin will show an increase over May. Sales for 1921 have been away ahead of the first 5½ months of 1920. Collections are good.

Dodge sold as many cars the week following the price cut as ordinarily would be disposed of in two months.

Briscoe Reports Gains

Although there has been no cut in price by Briscoe, sales have increased in the last two weeks and are much better than in May or April.

June is running better than April or May for Buick than all three months last year. The Chicago company has received a consignment of 500 cars and expects to clean them out in the near future.

Other companies which report that June business is better than April or May include Mitchell, Gardner, Lexington, Hudson and Essex.

Those which say that June is equal to that of either April or May include National, Packard, Haynes, Allen, Sayers, Handley-Knight, Stevens-Duryea, Pierce-Arrow and Peerless.

Reports on Business Conditions Continued on Page 1401

Buick Re-enters Automobile Field

Pioneer Named Head of Lorraine Motors

Will Make New Car at Grand Rapids Plant—Amassed Fortune With First Product

DETROIT, June 20—David Buick of Detroit, founder of the Buick Motor Co. of Flint, has re-entered the automobile business as head of the Lorraine Motors Corp. of Grand Rapids, and has designed a new car which will be put on the market shortly. The car will be marketed as the Lorraine, although it will be an entirely different product from that which the Grand Rapids organization has been manufacturing.

Buick and his associates have secured a controlling interest in the Lorraine Motors Corp. and a strong organization already has been perfected. A. H. Wyatt, well known in automotive and financial circles in Michigan, will be associated with Buick, in addition to John J. Larkin, former sales manager of the Haynes Automobile Co. of Kokomo, Ind., who will be general sales manager, and William Hulin of Grand Rapids.

The new car, which, it is promised, will rank with the higher priced cars in body design, will sell for less than $1,200, according to an official of the company. It will be equipped with a valve-in-head engine. Buick being credited with having brought out the first engine of that type.

Since leaving the Buick organization, although interested chiefly in carbureter production, Buick has continued to experiment with engines, and the one installed in the new Lorraine is declared to include several new features. The new car will have a 115-in. wheel base and will be equipped with a carburetion system thoroughly tried and tested under Buick's direction. The first car is being assembled and will be shown at Grand Rapids within a few weeks.

Buick left the company which bears his name in 1909, after six years spent in developing it, during which time he and his associates amassed fortunes. The Buick Co. was started with a capital of $37,000, and stockholders were made wealthy when the General Motors organization was formed with Buick as a central company.

R. A. A. BACKS TOWNSEND BILL

NEW YORK, June 20—Joining forces with the National Automobile Chamber of Commerce and the Rubber Association of America, the Motor and Accessory Manufacturers Association, has sent to its members a bulletin in which it declares that the United States highway policy has reached the cross-roads and that Congress must decide whether it will adopt President Harding's recommendation for a Federal highway commission as proposed in the Townsend bill, or let things drift. The bulletin states that to eliminate the plan for a Federal highway commission, as suggested in other legislation introduced in opposition to the Townsend bill would be to rob America's new road policy of its essential strength and efficiency.

Makers and Dealers Meet Again June 30

NEW YORK, June 20—The second of the series of conferences between committees representing the National Automobile Chamber of Commerce and the National Automobile Dealers' Association will be held June 30 at the Detroit Athletic Club. William E. Metzger has been appointed chairman of the N.A.C.C. committee which was headed by W. C. Sills of the General Motors Corp., until he retired from the Chevrolet company to become distributor for the New England territory. While Metzger is a vice-president and a large stockholder of the Columbia Motors Co. he looks upon the problems of the dealer from a sympathetic viewpoint for the reason that he is a member of the company which distributes the Willys-St. Claire car in Detroit.

Employment in May Shows 4.4 Per Cent Gain

WASHINGTON, June 20—Employment figures for the month of May compiled by the Bureau of Labor Statistics showed that there was an increase of 4.4 per cent in the number of men employed in the 46 automobile plants from which reports were received. The number of employees in April was 83,566 and last month it was 87,266. The number of employees in May, 1920, was 128,982.

In its discussion of the automotive industry, the report says:

"In this industry market conditions have improved since April and the per capita earnings show an increase of 4.9 per cent when comparing April and May figures."

The only other industries which showed an increase in employment for May over April were cotton manufacturing, cotton finishing, hosiery and underwear, woolen leather and boots and shoes.

WHITE WINS TAX DECISION

CLEVELAND, June 20—In a decision handed down in Common Pleas Court this week by Judge Manuel Levine, the White Motor Co. was adjudged within the Ohio personal property tax law in deducting its Federal tax due from its total credits.

Goodyear Cuts Price On All Truck Tires

Reductions Range from 10 Per Cent on Cushion Tires to 23½ on Pneumatics

AKRON, June 20.—The Goodyear Tire & Rubber Co. has made sweeping price cuts on all motor truck tires, including both solids and pneumatics and also cushion truck tires, effective to-day. The Goodyear price cuts will average 23½ per cent on all six, seven and eight inch cord pneumatic truck tires, including the sizes most generally used on trucks and buses. Reductions on all Goodyear S V solid tires will average 12 per cent and on cushion tires the cut will average 10 per cent. Prices on pneumatic tires for trucks over eight inches and on the new all weather solid tires for trucks will also be reduced to some extent.

Goodyear is the first major tire company in the United States to announce price reductions on truck tires. Practically all companies have reduced automobile tire prices, but none outside of Goodyear so far as revised prices on pneumatic and solid motor truck tires.

"These reductions will complete the stabilization of tire prices through the entire Goodyear line, following the reduction in prices on all kinds of automobile casings and tubes announced last month," says a Goodyear statement on the subject.

Goodyear to-day recalled 1200 of the tire builders who were laid off several weeks ago. Goodyear has completely revised its announced plans for closing down the factories from June 24 to July 5 for semi-annual inventory and will keep most departments running through that period, closing them only long enough for a hurried invoice. The steady increase in dealers' orders makes necessary the rehiring of several hundred men, officials state.

Dealers' Orders Increase

Three weeks ago Goodyear announced the tire industry apparently had entered a new slump. This, it was said, had been brought about by automobile manufacturers reducing their original equipment specifications. Dealers' orders have continued to increase, however, and Goodyear reports its dealer business now will compare favorably with normal dealer business for any time in the company's history.

Goodyear declares the increase in dealers' business does not assume the phase of a spurt, but justifies the belief that business will hold up in a stabilized way and will warrant putting on more men and increasing production.

Body Makers Discuss Needs of Industry

Credits, Contracts and Inventories Considered at Detroit Convention

DETROIT, June 18—Unethical practices of customers, labor problems and wage adjustments, liquidation of inventories, raw material prices and problems of financing occupied the time of the members of the Automobile Body Builders' Association at the convention which closed yesterday.

In opening the convention, following the meeting of the executive committee Thursday morning, President E. J. Thompson, of the E. J. Thompson Co. of Philadelphia, announced that no set program had been fixed, the conditions existing in the industry at this time calling for intimate discussions and the viewpoints of all present rather than the usual addresses dealing with generalities. On account of the vital problems confronting the association and the intimate questions to be taken up, he asked for an expression regarding the advisability of a closed session, and upon motion of A. R. Guider of Detroit, the 30 members present voted to exclude all but members and a few manufacturers "invited" to participate in the sessions.

A great portion of the discussion, officials said after the meeting, centered on problems of finance. Experiences of the members in satisfying their banking connections were heard and suggestions offered for closer relation with the financiers and a spirit of more hearty co-operation in furnishing them every bit of information on which to base credit. Methods of emergency fianancing—where to get money and how to make the most of a firm's capital, also were dwelt upon at length. Chief interest, however, centered in the matter of frankness with the banker as certain to assure extension of credit where deserved.

Find Practices Unfair

The cancellation of contracts by customers and the question of past due accounts came in for serious consideration, and practices that were declared to be most unfair were shown by members in detailing their various experiences. Questions of how best to overcome the evil and the formulation of a definite policy were discussed, but no formal action taken.

The matter of uniform sales contracts also was brought up and much time was consumed on the question of establishment of repair agencies throughout the country. Bad paint jobs, due to various causes other than poor material or inefficient workmanship, brought forth much discussion and suggestions for remedies.

The liquidation of inventories was urged as the all-important question before the association, and this brought to the front the problem of prices of raw materials now as compared with last fall, and the effect of those prices on production and sales costs. Standardization of materials and the extent to which raw material manufacturers will go in financing body builders, also were discussed.

Cost of production and the influence of present labor and wage conditions were gone into, and while it was the consensus that labor efficiency has increased more than 50 per cent, further wage recessions to meet demand for reduced prices were held imperative. Problems of administration as affecting the production end also were taken up.

Members of the association following the meeting said the time was spent almost wholly in discussions, and no action of definite nature taken on any of the many problems brought out.

Legislative Activity Important, Says Graham

NEW YORK, June 17—George M. Graham, vice-president and sales manager of the Pierce-Arrow Motor Car Co., was the principal speaker of the evening at a dinner of the New York Conference of Business Paper Editors. Speaking on business, its obligations and opportunities, Graham cited some illuminating facts about the tremendous wealth of the United States, as compared with its indebtedness. He showed that indebtedness is $24,000,000,000, from which $10,000,000,000 may be subtracted as representing our loans to the Allies, while the national wealth is at least $225,000,000.000 and, in the opinion of some authorities, $350,000,000,000. Graham observed that the United States decidedly was a "going concern."

Graham declared that business must be constantly alert to present its case correctly before government authorities, citing the recent effort of the automotive industry to bring about reduction or at least prevent increase of "stigma" taxes and pointing out the surprise of Senators and Representatives when they were shown for the first time, the essential nature of the industry. Business would suffer less from discriminatory legislation, the speaker said, if it would take the pains at all times to make sure that the public and officials understood its motives and accomplishments.

OHIO STARTS IMPORTANT ROAD

YOUNGSTOWN, OHIO, June 21—Work has been started on one of the most difficult and important highway jobs in the State in Wayne, Ashland and Knox counties. It will bring this city into closer touch with Columbus and Cincinnati, and the road will be an important link in the Lincoln highway. The estimated cost is $2,250,000. It is expected that all the 48 tractors owned by the State will be used as well as 75 more trucks and a dozen large steam shovels. State Highway Commissioner Herrick will have personal charge of the work and Major Adolf Stellhorn, highway department engineer, will be second in command.

Reserve Board Bans Import Parts Loans

Holds Goods Not Readily Marketable Within Meaning of Federal Act

WASHINGTON, June 18.—According to an opinion expresed by the Federal Reserve Board here to-day, renewal acceptances to finance the subsequent storage and resale of automobile parts imported from France are ineligible for acceptance by national banks. The Board was advised that "a national bank makes acceptances covering the importation of automobile parts from France, with a maturity of 90 days, which is supposed to be sufficient to cover payment for the merchandise in France, its transit to New York, its warehousing, and subsequent sale from warehouse. It is found, however, that before the transaction has been completed by the sale of the merchandise, that the 90-day period has expired."

In reviewing the case, the Board said that it appeared from the letter that the importer was drawer of the original drafts and was to be the drawer of the renewal drafts and that at the maturity of the original acceptances the parts had already arrived in the United States and were stored in warehouses pending resale by the importer.

It was said that section 13 of the Federal Reserve Act does not confer authority upon national banks to accept drafts growing out of the storage of goods other than "readily marketable staples," and automobile parts cannot be regarded as readily marketable staples within the meaning of this section. Consequently, if the drafts are to be secured by warehouse receipts covering the automobile parts, that fact would not of itself make the drafts eligible for acceptance by national banks. The drafts are eligible for acceptance only if and upon the ground that they can be said to grow out of the importation of the automobile parts within the intent of section 13.

McSHERRY IN RECEIVERSHIP

SPRINGFIELD, Ill., June 17—Alleging that the McSherry Mfg. Co. has liabilities exceeding $175,000, L. N. Rosenbaum, of New York City, filed a petition for receivership to protect his credits of $27,000. Judge E. S. Smith has named Joseph F. Bunn and E. H. Holbrook receivers. The petition sets forth that under the receivership, the firm with $400,000 assets will be able to meet its creditors. Capital stock is $1,400,000.

JOIN MOTOR TRUCK MAKERS

CHICAGO, June 18—The Atterbury Motor Car Co., Buffalo; the Federal Motor Truck Co., Detroit; the Selden Truck Corp., Rochester, and the Stewart Motor Truck Corp., Buffalo, recently have become members of the Motor Truck Manufacturers' Association.

Endurance, Economy; Most Sought in Car

N. A. C. C. Poll Shows Price Consideration Ranking Fourth—Speed Little Sought

ATLANTA, June 18—"Endurance is the most popular, and economy the second favored feature of the motor car, according to a nation-wide poll of motorists," said J. C. Long of the National Automobile Chamber of Commerce, speaking before the Associated Advertising Clubs of the World in session here.

"Comfort is the third consideration, followed by price. Speed and distinctive refinements have little interest for the average purchaser.

"These conclusions are the compiled returns from question cards sent to car owners in all sections of the United States by the National Automobile Chamber of Commerce, asking motorists to express their relative preference concerning the following features of a car: Appearance (general), appointments, comfort, economy, indorsement of other owners, endurance, flexibility, hill climbing, price, service (good local repair shops), specifications, speed."

"Buying points," said Long, "rather than selling points, are the important considerations to-day; and this poll of the customer should prove a helpful guide to both engineer and advertiser.

"Returns from 20 States, covering more than 30 makes of cars, on the index basis of 100 give the following emphasis to the different buying points:

Endurance 15; economy 14; comfort 9½; price 9½; appearance 8; service 7½; hill climbing 7; flexibility 6½; endorsement of others 6½; specifications 6; speed 5½; appointments 5.

"Fifty-one per cent of the voters said they were not interested in slogans. Forty per cent did not comment on this point, and of the remaining 9 per cent many specified that they were interested in lines which referred to motor transport in general, such as 'Drive Carefully.'

"Twenty-three per cent of this poll expressed an interest in specially featured parts, such as motors and springs, but 48 per cent were not interested, and 29 per cent were non-committal."

REES BUYS ATTICA PLANT

COLUMBUS, June 21—The Rees Motor Co. has purchased the plant of the Halladay Motors Corp. at Attica, Halladay having moved to Newark, Ohio, and it is the intention of the Rees organization to build a four-cylinder passenger car to sell for $1,450. The bore will be 2¾ in. and stroke 5⅛ in. Ignition will be by Atwater Kent system and the starting and lighting, Dyneto.

PAIGE ADDS DAYTONA ROADSTER

DETROIT, June 18—Following the record made at Daytona by the Paige 6-66, the Paige-Detroit Motor Car Co., has added a new body to the line on that chassis, this to be called the Daytona Roadster. It is primarily a sportsman's job but the skeleton equipment ordinarily found on racy-type models is replaced with comfortable seats and equipment. There is an auxiliary seat on the side of the body with foot rest on the aluminum step. Wheels are wire with 33x4½ cord tires. The finish is deep red for the body, wheels enameled in blue and other running gear black. Other equipment includes bullet side lamps, cowl ventilator, safety latches on doors, electric clock and muffler cutout.

Lexington Cuts Prices $200 to $600 on Line

CONNERSVILLE, IND., June 20—Reductions in the prices of its cars were made to-day by the Lexington Motor Co. The reductions, ranging from $200 to $600, will be effective immediately. They cover all Series "S" and Series "T" models, the former being equipped with Continental motors and the latter with the Ansted engine which was used in the Lexington specials that won both first and second honors in the two major events at the Pikes Peak hill climb last Labor Day.

Comparative table of new and old prices follows:

Models	New	Old
"S" Touring Car	$1885	$2285
"S" Thorobred	1985	2285
"S" Lex-Sedan	2185	2785
"S" Coupe	2750	3250
"S" Sedan	3150	3350
"T" Touring Car	2785	2985
"T" Sedanette	3750	4150

Martin-Parry Reduces Prices on Ford Bodies

NEW YORK, June 20—The Martin-Parry Corp., manufacturers of light commercial bodies with plants at York, Pa. and Indianapolis, has made another reduction in the prices of commercial and farm bodies for Fords. This reduction amounts to 10 per cent on certain models and became effective to-day. The Martin - Parry factories are operating on a good volume of production and officers of the corporation are confident that the business of their dealers and branches will be stimulated by this price revision.

STANLEY MAKES BIG CUT

BOSTON, June 16—The Stanley Motor Carriage Co. of Newton announces a cut in prices of all models of the Stanley car, the reduction averaging 33⅓ per cent. The reduction on the open models announced to-day is $1350 and follows a cut of $925 which was made last October.

PAN AMERICAN PRICE CUT

DECATUR, ILL., June 20—Prices on Pan-American cars have been reduced $250, the new prices to become effective at once. Both the roadster and touring car are now priced at $2,000.

Many New Models to Make Fall Bow

Era of Keen Competition Seen in Efforts to Induce Sales—G. M. C. Lines Active

NEW YORK, June 20—Much interest is being manifested in the industry in the unusually large number of new models which will be brought out in the late summer or early fall. They presage a new era of keen competition which close observers believe will give a new stimulus to the automotive trade. These new models are evidence that the manufacturers do not propose to depend entirely upon price inducements to get business.

The General Motors Corp. will be particularly active in the presentation of new models this year, and they will take in practically all the General Motors lines, including Cadillac, Oldsmoble, Scripps-Booth and Buick.

There is much speculation concerning the Durant line, which will be put on the market in the fall. The Durant four cylinder car has been promised for Aug. 1. Preliminary work on it has been completed and persons who have seen the car declare it a very high class job for the price at which it will sell.

The Sheridan, which recently was purchased from the General Motors Corp., will be converted into a six cylinder instead of a four. Experimental work on it is now under way at Long Island City. Except for the engine, the car will be practically the same as at present.

Experimental work on the Collins car now is being carried on in Detroit by R. H. Collins. The car will be developed along lines of his own and he will be given a free hand by Durant.

Reports from Detroit are to the effect that orders for the Lincoln car are coming in faster than they can be filled. The Lelands had considerable difficulty in really getting under way, but now that business actually has been given a substantial start, the car is creating something of a sensation.

The new Chrysler six which will be turned out at the big new plant of the Willys Corp. at Elizabeth probably will be put on the market in the late fall. It is understood that experimental work on it has been virtually completed and that it is entirely satisfactory to the Willys organization.

SARLES DUESENBERG WINS

GERMANTOWN, Pa., June 18—Roscoe Sarles, driving a Duesenberg car, won the 225 mile trophy race at the Uniontown speedway to-day. He averaged 97.75 miles an hour. Eddie Hearne, in a Revere Special, was second. His average was 97.25 miles an hour. Eddie Miller in a Duesenberg was third; Tom Alley in a Frontenac fourth; Alton Soules in a Frontenac Special fifth; Jimmie Murphy in a Duesenberg sixth; Frank Elliott in a Leach Special seventh, and Tommy Milton in a Frontenac eighth.

Buick Extends Work to Meet Heavy Sale

Production Now Over 250 Daily —Expect Steady Operation Through Winter

DETROIT, June 18—Orders are coming in from all sections of the country in good volume according to Buick Motor Co. officials. As a result production has been increased slightly and General Sales Manager E. D. Strong said to-day the plant now was hitting better than 250 daily. This is slightly in excess of the output for the past two months which ranged between 200 and 250. A driveaway of 500 cars destined to the Chicago dealers left the Buick factory Wednesday.

More than 11,000 employees now are at work in the Buick factory, according to President Bassett, and the factory is operating practically on a normal time schedule. Demand for cars has taken a decided leap, President Bassett said, and in increasing production it will be the policy to increase the working hours rather than add men to the force.

Despite the sharp jump in the sales demand, Buick officials are not to be stampeded and Sales Manager Strong said production at all times would be strictly in conformity with demand. "We are going to continue operation under this plan of building and we expect to be working next winter as steadily as we are to-day," said Strong.

Cars for all adjacent cities are being driven away from the factory, but the more distant points are being served by the railways. On Wednesday, the same day the 500 cars left overland for Chicago, a shipment of 300 was sent out by train to eastern dealers.

While all of the factories which have announced price cuts have reported increases in orders, the few which did not join in the price slash also declare they are experiencing good business right now.

Ford Sales on Coast Run Far Ahead of 1920

PORTLAND, ORE., June 18—Nearly 50 per cent more new Ford cars were sold in the city of Portland during the period from Jan. 1 to May 20 this year than during the same period of last year. In that time a total of 1212 new Fords were delivered by the Ford factory branch to the six authorized retail Ford dealers of this city. The Ford branch is now 355 cars behind.

Last year, for the same period, 851 Ford cars were delivered, this spring's business showing an increase over last of 361 cars, or an increase of about 40 per cent. Sales throughout the entire state of Oregon show a distinct increase for the Ford this year. Taking the state as a whole each month from January to June has shown an increase of from 40 to 62 per cent.

WAGON MAKING DROPS TO HALF 1914 TOTAL

WASHINGTON, June 18—A preliminary statement of the 1920 census of manufactures with reference to the manufacture of carriages and wagons, together with the materials used in the production of the completed vehicles, shows that the number of establishments engaged in this industry is rapidly decreasing. Reports were received from only 2666 in 1919, as compared with 5286 in 1914. The number of vehicles manufactured in 1919 was 695,200, valued at $66,083,000, as compared with 1,177,400 valued at $72,284,000 in 1914. The decline in the industry is due almost exclusively to the increasing use of passenger automobiles and motor trucks.

Vim Truck Operating on 14 a Day Basis

PHILADELPHIA, June 18—Formal announcement is now made by the Vim Motor Truck Co. that it has been taken over by the Standard Steel Car Co. of Pittsburgh and is now being operated as a subsidiary of that concern.

Harold B. Larzelere, vice-president and general manager of the Vim Motor Truck Co., will continue in that office. He says that the plant is now working at about 20 per cent of capacity and producing 14 trucks a day.

The Standard Steel Car Co. manufactures steel cars and automobiles and, in addition to its interests in the Vim company, controls the Middletown Car Co. and the Baltimore Car & Foundry Co. John M. Hansen, the president, is also a director and a member of the executive committee of the Baldwin Locomotive Works.

ONEIDA INCREASES OUTPUT

GREEN BAY, WIS., June 18—The Oneida Motor Truck Co. resumed operations on June 6 on a production schedule of 30 to 50 trucks per month, with a working force of about 60 per cent of the normal prior to the shutdown several months ago. Shortly after Jan. 1 it was found necessary because of business conditions to reduce the force 75 per cent or more. New business booked during the last six to eight weeks and orders for future delivery have enabled a resumption.

DUPLEX EXTENDS OUTPUT

LANSING, MICH., June 20—Renewed activity is shown in the plant of the Duplex Truck Co., which now is running three full days each week. Developments at the plant lead officials to believe the next two or three months will show rapidly increasing business. A recent order for three passenger motor buses from the South Bend-Elkhart Motor Bus Co. is reported as an encouraging sign.

Thousands to Attend Fargo Tractor Test

Leading Companies Enter Machines for Demonstrations of Power Efficiency

CHICAGO, June 20—Reports from Fargo, N. D., indicate that the demonstration of tractor and horse farming, scheduled for that city June 28, 29 and 30, is attracting wide interest in the Northwest and that a big crowd of farmers and dealers will attend the demonstration. The fact that an effort will be made to show the efficiency of the average tractor and that horse teams will be put at the same work as tractor outfits, not in competition, but in such manner as to leave the onlooker free to draw his own conclusions, has aroused wide interest.

The expectation of large crowds is borne out by the demand made upon the housing facilities of Fargo. There is reason to believe that the capacity of the city will be taxed and hundreds of farmers are planning to drive to the demonstration with their families and camp out along the Red or Cheyenne rivers for the three days of the demonstration. Excellent camping facilities have been provided.

Among the companies that will be represented are the following: International Harvester Co., Avery Co., Emerson-Brantingham Co., Aultman & Taylor Machine Co., Advance-Rumely Co., Rock Island Plow Co., J. I. Case Plow Works Co., J. I. Case Threshing Machine Co., Hart-Parr Co., Eagle Mfg. Co., Liberty Tractor Co., Meadows Mfg. Co., Oliver Chilled Plow Works, Ford Motor Co., American Industrial Development Corp., Paris, France; Hyatt Roller Bearing Co., Timken Roller Bearings Co., Cole Mfg. Co., Minneapolis Steel & Machinery Co., Townsend Mfg. Co.

MOTOR PARTS PLANT STARTS

BRISTOL, CONN., June 18—Motor Parts Corp. has bought the Garrigus plant on Riverside Avenue from the Bristol Machine Tool Co. and will manufacture parts for automobiles. The Bryce plant in Forestville has been taken over by the new concern, which was recently capitalized at $1,100,000 and, commencing to-day, will begin operations with a full complement of employees. Residents interested in the corporation are Frederick N. Manross, John F. Wade, John W. Bryce, Charles H. Curtiss and Roger S. Newell.

REPORT TRADE IMPROVEMENT

SPRINGFIELD, OHIO, June 18—At a conference held recently with E. H. Gilcrest, general sales manager for the Westcott Motor Car Co., the members of the sales force in attendance reported general improvement in business conditions is noticed and that there is a steady increase in sales. The Westcott company is increasing its force.

ALL SECTIONS REPORT SALES GAINS IN JUNE

Milwaukee

MILWAUKEE, June 18—The Ford Motor Co. branch here showed sales of 4000 cars in April, but this was limited by capacity and output. May sales were 5100 cars and June is certain to reach the same figure. Sales for July are expected to reach 4000. This branch covers 51 counties, or the largest part of Wisconsin. The Milwaukee Retailers' Association is just completing a survey of the local field. President Tom C. McMillen, who heads Overland sales here, said to-day:

"General business conditions in Wisconsin apparently are better than in adjoining States. This is reflected in the automobile market and affects all priced cars favorably except those that have not revised price schedule. Distributors are finding the market good immediately following price reduction announcements. The increased sales in Milwaukee clearly demonstrate that the public was waiting for reductions."

Minneapolis

MINNEAPOLIS, June 17—No doubt exists that the automobile business has improved the first half of June over the two preceding months. A difference of opinion exists as to the percentage of gain. One of the biggest distributors of moderate priced cars put the gain at 30 per cent. At the branches and agencies where prices have been cut and where some models have been out of alignment, especially in the smaller popular sizes, the new prices have stimulated buying. Business still is better in the larger towns than in the country districts for the money situation has not loosened up enough yet to make large buying possible to small dealers.

Des Moines

DES MOINES, June 17—June retail sales show material improvement over April and May. Conservative dealers attribute this to stimulation of business by price cuts. Those cars which made cuts during the past 30 days have had a brisk business. Dealers are perplexed as to whether or not stimulation is permanent or temporary but are inclined to believe that the next 30 days will see more or less activity followed by a letting down, although the stagnation of spring is not expected. Two distributors whose companies made material price cuts report their stocks completely cleaned out.

Kansas City

KANSAS CITY, June 20—Dealers whose prices have been reduced are selling cars in volume—one such dealer being reported to have accumulated orders for delivery as late as August 1.

On the other hand, some dealers who have guaranteed prices for the year are said to be in an embarrassing position, with sales temporarily almost suspended, and danger to them whether the price is cut or not.

Weather has been good for country driving, with renewed interest in motoring, and consequent increase of attention to cars by prospective purchasers, the chief benefit accruing to country dealers.

Columbus

COLUMBUS, June 20—Under the stimulation of price reductions and better industrial conditions, business in passenger cars in Columbus and central Ohio territory has shown remarkable increases in the past few weeks. Practically all dealers are sharing in the better business.

The public apparently had been waiting for the reductions and immediately stepped into the market and purchased freely. Dealers report a larger number of prospects, many of which are considered high class and likely to be new owners.

In the rural sections there is still some slowness reported although some increase in sales is reported from the dealers in the larger towns. Farmers are now busy with their crops and have little time to look around. With their crops in, it is believed there will be better business in the rural sections.

The truck business is still quiet and the public is apparently waiting for price reductions.

Indianapolis

INDIANAPOLIS, June 17 — Retail sales here show a slight improvement thus far in June over April and May of this year. The average increase is about 10 per cent. The increase actually is more marked on those cars in which price reductions were made. Dealers in handling cars on which price reductions have been made say that for a month or six weeks following cuts a decided increase in sales can be seen but the rate soon decreases. Larger increases are shown by the medium and low priced cars. Dealers in high priced cars report only a slight increase over the two preceding months and in some cases no increase at all.

Boston

BOSTON, June 17—Retail automobile sales during the past few weeks have improved compared to April and May. The dealers whose makers had cut prices found that people who had been holding off came in and closed up orders. There were a number of new orders booked from others who were not on the lists of prospects. All dealers have not been selling as largely as a year ago, of course, but when an average is made of the entire motor district, balancing up the sales of high and low priced cars, and those which have cut with those which have not, the conditions in the trade are much better than a month ago, when there was a lull after the show orders and prospects had been cleaned up.

Portland, Oregon

PORTLAND, ORE., June 18—Sales of new automobiles in Portland during May totaled approximately one and one-half times as many as during April, according to the record of new licenses secured during the two months. Whether June will show further increase or will run behind May in volume is matter of speculation and too early of determine. The record of new licenses, while not showing absolutely in volume of sales for new cars, forms an excellent basis of comparison. According to the record April sales of new cars totaled 444 while May sales totaled 681. In each case slightly over half were Fords.

Recent price reductions have increased activity in some lines, particularly Dodge, but daily license reports indicate that so far all makes concerned reductions have had no marked effect yet in total sales.

Los Angeles

LOS ANGELES, June 17—Stimulated by price reductions, retail automobile sales now are more numerous than in the corresponding period of May or April but indications are that this condition will not continue long. Immediately following price changes, salesmen bore down on every prospect who could be swayed and obtained signed orders. This number now is about exhausted and already a slackening is evident. Business right now is very good and June will be an excellent sales month but southern California has led the entire United States throughout the year and the present cannot be taken as a criterion for the future when the existing impetus will have passed.

Denver

Denver, June 18—Automobile sales in the Rocky Mountain territory have been upset by abnormal conditions due to price unrest and disastrous floods. Some distributors who had a big April and May, report June sales about 40 per cent as good. Some are better and many worse. Few lines are gaining through the new price drop while others are losing in same price class without a drop. Intensive selling is helping two particular makes with price stabilized since a reduction in January. Dealers take the view that the unrest and readjustment are inevitable and hope for an early improvement.

Spokane

SPOKANE, WASH., June 20—The motor trade has improved substantially in Spokane and begins to approximate conditions before the slump. A point in case is the Marsh-Strickle company which placed 19 cars and trucks during the week ending June 4. Improved general conditions and the advent of exceptionally fine weather have combined to stimulate trading.

Durant Plans Ready for Plant on Coast

Will Have Capacity of 20,000 Cars Yearly—Will Not Buy Truck Company

NEW YORK, June 20—R. C. Durant, president of Durant Motors of California, started back to the coast to-day after a brief visit to this city for a discussion of plans for the Oakland plant. He was accompanied by C. M. Stevens, who will be sales manager of the California company.

A site has been purchased in Oakland for the assembly plant, which will have a capacity of 20,000 cars a year. Plans for the building have been practically completed. The factory will be similar in design to the main assembling plant on which work has been begun at Lansing. It will be about half the size of the Lansing plant, which will cost $3,000,000, and have a capacity of 40,000 cars a year. The Oakland building will be 600 feet long and will have three wings besides a large storehouse and an administration building, which will be located in front of the main plant.

The Durant plants at Lansing, Oakland and Long Island City all will be used for assembling. Practically all the parts of the car will be purchased from other manufacturers for the present, but Durant proposes ultimately to build many of them in a factory of his own. The location of this plant has not been decided upon, but it is quite possible it will go to Flint, which has been promised one of the Durant factories.

Reports that Durant contemplates the purchase of some widely known truck company are without foundation. He has not lost his faith in the future of commercial motor vehicles, but his interest will be centered for the present upon passenger cars. A line of trucks ultimately will be added to the Durant products, but it will not be until the outlook for sales in this field is brighter than it is now. He has definitely decided not to undertake the manufacture of tractors or other farm machinery.

Assertions made recently in Wall Street that Durant was buying stock of the Studebaker corporation for speculative purposes were incorrect. Most of the stock he bought was as an investment, and it is now held by Durant Motors, Inc., which is authorized as a holding company to buy the stocks and securities of other companies. It also has in its treasury a considerable quantity of General Motors stock.

Four Durant Companies to Issue Securities

LANSING, MICH., June 18—On account of the fact that Durant Motors, Inc., is to have four distinct branches, Durant Motors, Inc., a Delaware corporation; Durant Motors, Inc., of New York; Durant Motors, Inc., of Michigan, and Durant Motors, Inc., of California, the Michigan Securities Commission has issued an order that all brokers and salesmen for Durant Motors stock must designate to the purchaser in which of the four corporations the stock offered is included. At present two of the corporations are organized and approved, the Delaware and New York concerns. The proposed Michigan company has not yet been incorporated and the same is true of the California company. In each of these cases, however, the only difference is in the designation of the State in which the company is incorporated.

According to information given the Securities Commission, the Delaware company is the holding corporation of the Durant chain. The New York company will manufacture automobiles for the territory east of the Alleghenys. The California company will supply the Pacific Coast and Mexico, and all of the central part of the country between the mountain chains will be served from the Lansing plant where parts will be manufactured and cars assembled.

At present only Durant Motors stock of the Delaware corporation is being offered in Michigan.

Reo Opens Coast Branch, Sales Officials Change

DETROIT, June 20—Several changes are announced in the Reo organization, including the establishment of a branch house in San Francisco to handle business in California and along the Coast, and to serve as an export basis for the Pacific islands and the Orient. Carl Parker, manager of the Lansing-Reo branch, has been transferred to the sales organization at the factory and is succeeded by George Hopkins.

The California branch will be managed by P. L. Emerson, who has been an assistant to Sales Manager R. C. Rueschaw and an auxiliary to the branch in California, a large wholesale and retail establishment in Los Angeles will be under the management of Byron C. Foy, now assistant manager of the Detroit-Reo branch. C. P. Green of the engineering department will be in charge of service at the San Francisco branch. Establishment of the Western branch completes a chain in Reo branch houses extending across the continent, the others being at New York, Detroit and Chicago.

MACK BRANCH FOR HOUSTON

HOUSTON, TEX., June 20—The International Motor Truck Corp. is planning to establish a factory branch here. This was announced this week when J. George Truelson, formerly of Dallas, was made district Southwestern manager for the company. The branch here will take care of business in Mexico and the Southwest generally, it was said. Company officials declare there is a fine business prospect in Mexico and the rail and water shipping facilities here cause the factory branch decision. The company has factory branches at Dallas and Fort Worth.

New Driggs Car Near Manufacturing Stage

New Haven Product Is Designed for Fuel Economy—Weight 1600 Pounds

NEW HAVEN, CONN., June 21—The production of a new four-cylinder car will shortly be started at the New Haven plant of the Driggs Ordnance & Mfg. Corp., of which L. L. Driggs is president. The car is called the Driggs and sells for $1,175 in the touring model and $100 more for the special roadster. The Driggs Ordnance Mfg. Corp., while a newcomer in the automobile manufacturing field, has behind it extensive experience in the manufacture of ordnance and automobile parts.

The new car has been designed for minimum gasoline consumption. While rated at about 11 S.A.E., the engine actually delivers 18 hp. The bore is 2⅝ and the stroke 4½ inches. Several tests made with the experimental cars convince the manufacturers that the machine under tolerably good conditions will run at least 30 miles to a gallon of gasoline. When fully equipped, the car weighs only a trifle over 1600 lb.

The engine is three points suspended. Ignition is by battery, with the option of a magneto for use abroad. Lighting and starting are by the Gray & Davis system. The clutch is a Borg & Beck dry disk, while the transmission is of the selective type, with three speeds forward and one reverse. Service brakes are of the contracting type, emergency brakes expanding.

The front springs are semi-elliptic, but the rear springs are of the cantilever type, extending from the rear end of the frame forward to the axle. The company will manufacture its own rear axles, which are of the three-quarter floating type, with taper roller bearings. The front axle is the drop forged I-beam type, also with roller bearings.

The pump and splash system of oiling is used, and cooling is by the thermosyphon method. The gasoline tank, of 10 gal. capacity, is located in the rear, with vacuum feed to the carburetor. Steering is to be standard left hand, although the right hand drive may be had at an additional charge. All bodies (including a sedan) are mounted on the 104 in. wheel base chassis.

SEVERIN PETITION FILED

KANSAS CITY, June 20—An involuntary petition in bankruptcy has been filed in the Federal Court against the Mokaw Motor Co., makers of the Severin car, by the Equipment Co., the Mutual Motors Stores Co., the Ever Ready Tire & Service Co., the Thomas Cusack Co. and Price Cary, whose claims total about $1,500.

The Mokaw company succeeded the Severin Motor Co. several months ago. A hearing on the petition will be given next week.

Banks Arrange Plan to Finance Willys

Proposal Calls for Underwriting $20,000,000 in Mortgage Bonds at 8 Per Cent

NEW YORK, June 22—After a series of conferences extending over several months, the bank creditors of the Willys-Overland Co. have agreed upon a plan for refinancing the company in such a way that its overdue bank loans, amounting to $21,000,000, can be paid. The proposal calls for the underwriting by a strong banking group of approximately $20,000,000 in first mortgage, 8 per cent bonds. This will provide funds to pay the bank loans, and with the cash now on hand, which approximates $10,000,000, the company would be in a strong financial position.

It is assumed a similar plan will be adopted for the Willys Corp. and the Moline Plow Co., both of which are being directed by creditors' committees.

Announcement that this plan has been decided upon by the bankers' committee makes it evident that more than three-fourths of the preferred stock outstanding has given its consent. The preferred stock of all the Willys companies contains the provision that without the consent of 75 per cent of the amount outstanding no mortgage can be placed on its property and that neither the parent company nor any subsidiary company can place any mortgage on its property or create any stock having priority over or on a parity with the present preferred stock or dispose of any material part of its property. Preferred stock has preference as to assets as well as to dividends, and in case of voluntary liquidation is entitled to 110 per cent and accrued dividends.

The Willys-Overland preferred stockholders must consent to any similar plan for the refinancing of the Moline Plow Co., which is to all intents and purposes a subsidiary. Willys-Overland does not control the Willys Corp. Three distinct banking groups are involved in the transactions.

Chrysler Division Separate

Under the new financing plan, it is understood, the huge new plant at Elizabeth, N. J., where the "Chrysler six" is to be built will be made a separate division. It is now a part of the Willys Corp. but there is reason to believe it ultimately may be taken over by Walter P. Chrysler, executive vice-president of the Willys enterprises.

Another plan under serious consideration is the merger of the Auto-Lite Corp. and the New Process Gear Corp., which also are parts of the Willys Corp.

The Elizabeth plant was nearing completion when the depression began and at the behest of the bankers production in it was deferred until the market outlook became more favorable. This project is one close to the heart of Chrysler but it is now about the only unprofitable Willys unit, for Auto-Lite and New Process Gear are reported to be doing an excellent business. If these two companies are merged and the Elizabeth plant sold to Chrysler, all the Willys enterprises may be brought together into one company under the original plan of the bankers, announced in AUTOMOTIVE INDUSTRIES several months ago.

Townsend Presses Senate for Passage of Bill

WASHINGTON, June 21—Senator Townsend is pressing the Senate for the immediate consideration of his bill to provide for the establishment, construction and maintenance of a post road and interstate highway system under the direction of a Federal Highway Commission. The reports of the majority and minority members of the Senate Committee on Postoffices and Post-roads were submitted to the Senate and were ordered printed on Monday. It is expected that the measure will be enacted within a few weeks. For the majority, Senator Townsend submitted the report favoring the continuation of Federal aid in the construction of highways for two years.

In discussing the need of highways and the importance of the motor vehicle, the committee stated:

"A new era in transportation confronts the United States. An evolution of far reaching social, political and industrial importance has been effected through the constantly growing use of highway transport. The modern vehicle has rendered obsolete old methods of highway construction. The question is no longer local alone in application; it is national. Obviously, our highway policies must be broadened and strengthened to meet this changed condition if public expenditures are to be conserved and the best interests of the nation cared for. Living costs can be reduced, our defense strengthened, and a new spirit of nationalism created, if we use intelligently this new means of communication between communities and states."

The report of the minority dissenting from the report of the majority was regarded as an appeal to prejudice in the interest of the farmers, and a defense of the present law which President Harding and others have condemned.

FORM NEW REYNOLDS COMPANY

DETROIT, June 17—The Reynolds Truck Co., Mt. Clemens, Mich., an outgrowth of the Reynolds Motor Truck Co., which went into receivership last spring, has been incorporated with a capital of $75,000 and approved by the Secretary of State. Albert Schott is president, Fred B. Schott, vice-president, and L. F. Wolf, secretary-treasurer. These officers were stockholders in the old concern. Charles Kennan of the Service Garage at Mt. Clemens, who purchased the property of the former company, is sales manager. Kennan said yesterday there is sufficient material on hand to permit the manufacturing of 150 trucks.

Big Plants Speeding to Meet Sales Push

Notable Increases Are Made at Dodge and Chevrolet in Recent Weeks

DETROIT, June 21—The influence of recent price reductions is reflected in increased production in Michigan factories, notably Dodge and Chevrolet. The big Dodge plant is turning out an average of 425 daily as compared with an average of 288 in May. Chevrolet is maintaining its schedule of 176 daily against an average of 118 in May. Buick, which ran around 250 daily in May, now is hitting near 300.

Ford is running to capacity, maintaining an average of 4100, and Ford officials said the present schedule would be maintained indefinitely. Paige, according to W. K. Towers, advertising manager, is keeping to its schedule of about 35 daily which was also the May average. Packard is building on a schedule of 1000 single sixes in June as compared with 800 in May, and Cadillac is running about the same as last month, which is around 55 daily.

Studebaker is producing about 335 daily in Detroit and South Bend against 292 in May. A slight increase is reported at the Oakland factory and by Hupp. Olds Motor Works are producing at about the same ratio as in May, though the month's total will be greatly increased because the plant was down several days in May. Reo also is continuing on its May schedule.

The Maxwell and Chalmers plants, which built 50 and 20 daily in May are now producing in conformity with the increased demand though officials will not give out actual figures. Brisk demand for Hudson and Essex compelled a speeding up in production and officials say reports from all sections indicate an improved market. One train of 40 cars left the factory for Chicago last week carrying Essex touring cars.

Tire Makers to Promote Straight Side Use Abroad

NEW YORK, June 22—Subjects of interest to the entire industry were discussed at a meeting of the executive committee of the tire manufacturers' division of the Rubber Association of America at Atlantic City last week. One of the most important was the request of Secretary of Commerce Hoover that the association co-operate in the gathering of statistics covering inventory, production, sales and production capacity. Members of the committee expressed a willingness to work with the Department of Commerce so far as possible. Much interest was displayed in foreign trade and a program was adopted for the promotion of straight side tire sales in other countries. Discussion was continued on various phases of standardization.

Decrease in Exports Due to Short Credit

Automotive Shipments Abroad Far Below May, 1920, Figure —All Lines Hit

WASHINGTON, June 20—Further decline in the volume of foreign sales in automotive products is revealed in the report of the Department of Commerce on export conditions during May. The falling off of export business affected all branches of the trade because the sales of cars, parts and engines were at very low ebb. Foreign trade experts attribute the decline in all commodities to inadequate credit facilities and problems of international finance.

Despite the fact that promotors of foreign trade are optimistic, the economic story revealed by the statistical studies show other tendencies. For instance, shipments of commercial cars during May of this year numbered 462, with a value of $794,699, as compared with 3194 cars and a value of $4,858,026 for May of 1920. These figures show a slump of more than $4,000,000 in one item. Total shipments of trucks for the eleven months ending May, 1921, amounted to 17,180, with a value of $28,980,721, and for the same period last year there were 21,659 commercial cars exported with a declared value of $37,361,182.

Shipments of passenger cars fell off at a more alarming rate. The export records show that 2479 passenger cars with a declared value of $2,973,334, were exported during May, 1921, while in May, 1920, the exports of passenger cars amounted to 14,990, with a value of $16,434,244.

Exports of automotive parts, not including engines and tires, during May of this year, were valued at $3,204,723, as against $8,382,749 in May, 1920. Despite this reduction, the total value for the eleven months ending May, 1921, was greater than the corresponding period of 1920. The same condition exists in respect to airplane shipments.

The most significant decline in volume of engine reports was that of tractor engines, as exports for May, 1921, amounted to 18 engines, with a value of $34,108, as compared with 2286 engines and a value of $2,475,346. The eleven months total of 13,366 tractor engines stacked up fairly well with the corresponding period of last year, when 18,522 engines were sold abroad.

Exports of Automobiles, Airplanes, Trucks, Farm Tractors, Motorcycles and Parts for May and 10 Previous Months

	May				11 Months Ending May			
	1920		1921		1920		1921	
	No.	Value	No.	Value	No.	Value	No.	Value
Airplanes	17	$214,000	7	$29,500	59	$430,694	63	$446,455
Airplane parts	..	198,633	..	37,673	..	633,827	..	186,603
Commercial cars	3,194	4,858,026	462	794,699	21,659	37,361,182	17,180	28,980,721
Motorcycles	4,324	1,144,467	564	178,686	32,484	8,860,537	24,157	7,631,945

JUGO-SLAVIA HAS 2000 CARS

WASHINGTON, June 18—Official figures for the year ended April 24, 1920, showed the number of motor vehicles in Jugo-Slavia to consist of the following: Passenger cars, 1592; trucks, 274, and motorcycles, 290, according to a report received from Vice-Consul Don S. Haven, Belgrade. The figures do not include about 2000 cars of all classes under the control of the Ministry of War. A German concern has recently put 100 trucks on the local market, but a close estimate of the increase in motor vehicles for the past year does not exceed 400 passenger cars and 200 trucks.

New Interests Propose Angus Sanderson Deal

LONDON, June 10 (By Mail)—The British licensee for the Dutch Spyker car has come to the rescue of the Angus Sanderson Co. with a financial proposition which probably will be accepted. He proposes to build the Spyker car together with the Angus Sanderson in the new plant of J. Tylor & Son, Ltd., engine builders, at New Southgate. He agrees to buy the Tylor assets for $625,000, provide $450,000 to finance the project and guarantees unsecured creditors 25 per cent of their claims in cash and 15 per cent of the profits until they are liquidated.

BETHLEHEM TO MAKE WHEEL

BETHLEHEM, PA., June 22—The Bethlehem Steel Corp. is entering the automotive field with the development of a steel wheel for light and heavy motor trucks. This wheel is being made by a special process and has not developed to a point where it can be placed on a commercial basis, but experiments with the wheels are being made on trucks in various parts of the country and the results thus far have been so successful that the corporation expects to have the wheel on the market in a short time.

TO DRAFT OIL STANDARDS

WASHINGTON, June 21—Conferences will be held here July 2 by the Technical Committee on Standardization of Petroleum Specifications, for the consideration of specifications under which the Government purchases gasoline, fuel and lubricating oils.

British Trade Shows Heavy Falling Off

LONDON, June 10 (By Mail)—In May Great Britain imported 425 cars, 137 trucks and 305 chassis for cars and trucks, and 27 motorcycles. The respective figures for May, 1920, was (in the above order) 2593, 1254, 1146 and 193. The value of imported car and truck parts was $1,333,725, as against $2,212,565 in May, 1920, and of motorcycle parts $38,345, as against $45,100 in May, 1920. The value of the month's tire import was $70,290, against $1,575,205 in May, 1920.

The month's export of British automobiles and tires was ninety cars, of which 10 went to British India, 3 to New Zealand and 77 to unspecified countries; 73 trucks of all categories, of which 47 went to British India and 26 to countries not specified, and 94 chassis, of which 1 went to British South Africa and 93 to not specified countries. The corresponding export figures for May, 1920, were 248 cars, 71 and 226. The value of the month's parts' export was $635,715, against $841,225 in May, 1920.

The month's export of British motorcycles was 864, as against 1599 in May, 1920. The month's value of British motorcycle parts exported was $105,475, as against $238,660 in May, 1920. The value of British tires exported was $687,170, as against $2,415,880 in May, 1920.

DORT MAKES SECOND CUT

DETROIT, June 24—The Dort Motor Car Co. announces the second price cut in a month, effective immediately. The touring car and roadster are reduced from $1,115 to $985; the coupe from $1,685 to $1,535, and the sedan from $1,835 to $1,685.

It is understood that a reduction of $200 on all models of the Briscoe car will be announced July 2.

Business in Nation Close to 1920 Total

Volume of Sales in April Exceeds 1919—Some States Equal 1920 Figure

NEW YORK, June 22—Statistics of the volume in dollars of monthly purchases of all classes of commodities by individuals and business concerns in all the states of the Union, show that in a majority of the districts the volume for April, 1921, exceeded April, 1919, and that in some states it was almost equal to 1920.

The districts in which April sales for 1921 exceeded those for the same month in 1919 were New England, Pennsylvania, Ohio, Virginia, Georgia, Illinois, Texas and the Pacific Coast. They were virtually the same in the New York and Northwest districts. They were slightly less in the Missouri district.

Accepting the average of sales for April for a 10-year period as normal, April sales this year ran far ahead of normal except in the State of Delaware. The volume of April sales this year ran behind April, 1920, however, except in Arkansas and Wyoming. There was a very slight decline in California, Idaho, Nevada and Utah, and other states in which the falling off did not exceed 10 per cent were Connecticut, Delaware, Indiana, Maine, Maryland, New Jersey, Pennsylvania and West Virginia. The heaviest shrinkages were in Georgia, Kentucky, Louisiana, North Carolina, North Dakota, South Dakota, Tennessee, Mississippi, Nebraska and Washington.

Census Statistics Show Tire Growth Tremendous

WASHINGTON, June 18—Development of the automobile industry is reflected in the report of the Bureau of the Census on the manufacture of rubber goods in 1919 and 1914. The comparative summary shows that the total value of rubber products manufactured in 1919, in 475 establishments, was $1,138,216,000, as compared with 342 establishments and products valued at $300,994,000 in 1914. Of the 1919 total, pneumatic tires casings were valued at $485,904,000.

There were 39,700,000 inner tubes valued at $199,305,000 produced in 1919, as compared with 7.908,000 tubes, valued at $20,101,000, in 1914. Casings for motorcycles and bicycles produced in 1919 aggregated 3,422,000, with a value of $11,892,000. Inner tubes for motorcycles and bicycles in 1919 numbered 1,393,000, with a value of $2,904,000. Statistics show that solid truck tires amounted to 1,620,000, valued at $43,917,000, in 1919. All other solid tires total 6,635,000 and $9,005,000. The total production of solid tires of all kinds in 1914 was valued at $13,736,000. Rubberized fabrics for automobiles and carriages produced in 1919 amounted to 14,429,000 yd. valued at $10,697,000.

Ford Record Now 4322 Cars a Day

DETROIT, June 22—The Ford Motor Co. broke its 1921 record and all other motor vehicle records yesterday with a production of 4322 cars and trucks. The rate for the first half of June assures completion of the schedule of more than 100,000 for the month. Officials say the present output will be continued through July and as long as the demand keeps up.

Ferris Receivers Named, Will Continue Schedule

CLEVELAND, June 21—Federal Judge D. C. Westenhaver to-day appointed William E. Ferris and Norton McGiffin receivers for the Ohio Motor Vehicle Co. They gave $25,000 bonds each. The receivers were appointed upon the application of the Continental Motors Co. of Detroit which alleged in its petition that the Ohio corporation was indebteded to it in the sum of $32,880 for motors delivered and unpaid for.

Charles Riegler, president of the Ohio Motor Vehicle Co., stated that his company had insufficient cash on hand to pay its obligations as they mature. The obligations are placed at $175,000 by Riegler. He says the company is solvent and will pay all creditors in full if the assets are properly protected and are not dissipated. The physical assets of the corporation, exclusive of patents and good will, amount to $600,000.

The embarrassment of the company arises from the fact that it is no longer able readily to dispose of its products which consist of the Ferris automobile tractors and trailers. Most of the company's indebtedness now is for parts that have gone into the production of cars and tractors worth $250,000.

Riegler said that market conditions had hampered the company and that it had been sued by 20 different creditors, some of whom have obtained judgments. He asked that the receivers be given authority to conduct the business. Judge Westenhaver gave the receivers full authority to operate the plant and to sell its products. Word has been passed out to the trade that the corporation will promptly fill all orders, carry out all contracts and proceed as before.

EXPECT ORDER TO SELL COTTA

ROCKFORD, ILL., June 18—Trustees of the Cotta Transmission Co. expect within a week to receive a court order to discontinue operation of the plant and sell the property. Since the declaration of the company as a bankrupt, trustees were permitted to operate the plant under an order expiring June 1. Many creditors have signed a petition asking that the plant continue until Oct. 1 but no new orders are on hand.

G.M.C. Awards Stock Under Bonus Plan

Shares Totaling 123,884 Distributed to 6577 Employees for Work in 1920

NEW YORK, June 22—General Motors Corp. this week is awarding 6577 of its employees 6332 shares of the 7 per cent debenture stock and 117,552 shares of the common stock of the corporation as bonus for the calendar year ended Dec. 31, 1920.

The bonus plan was adopted in 1918 as a solution of the problem of how employees of exceptional merit might be induced to remain with the corporation for a period of at least five years. This profit sharing plan is also substantial recognition of the fact that in a marked degree the success of the corporation may be attributed to the inventions, ability, industry, service and loyalty of its employees.

Employees, by the operation of the plan, are made partners and part owners in the business and thereby encouraged to further effort and initiative. It is the intention to continue the plan year after year, the right being reserved, of course, to modify or repeal the plan at any time; however, a bonus once granted an employee cannot be recalled or modified.

The annual awards under the bonus plan are held in trust for the employee for a period of five years, but during that time dividends are paid direct to the employee. The awards for the three years during which the plan has been in operation follow:

Years Ended Dec. 31	Number Shares Common Awarded	Number Employees Receiving Common	Number Shares 7% Deb. Awarded	Number Employees Receiving 7% Deb.
1920...	117.552	3,210	6,332	3,367
1919...	214,659	1,721	14,088	4,709
1918...	261,460	2,277	....	....
G'd total	593,671	7,208	20,420	8,076

The corporation each year, after deducting from net earnings 6 per cent of the capital employed in the business, sets aside 10 per cent of the remaining net earnings and this amount of money is placed in the bonus fund, which is invested in the common and 7 per cent debenture stock of the General Motors Corp. The total amount of money set aside out of earnings in the three years, 1918, 1919 and 1920, with which to carry out the bonus plan work is in excess of $13,000,000, and this does not include the expenditures of administration.

ILLINOIS TRACTOR IN SUIT

BLOOMINGTON, Ill., June 18—Charging misrepresentation in sale of stock, S. W. Cramm, of Kansas City, has filed suit for $25,000 damage against the Illinois Tractor Co. and its Board of Directors. The bill alleges that Cramm subscribed to stock to the amount of $9,180. He said it was represented that the stock was worth $150.

U. S. Car Sales to Cuba Total $8,618,270 in 1920

HAVANA, CUBA (By Mail), June 20—A compilation of automobile imports from the United States shows that in 1920 they were valued at more than twice as much as in 1917. The following table shows the number and value for four years:

	1917	1918	1919	1920
Number	3446	2400	3935	5715
Value	$3,364,551	$3,394,830	$4,921,648	$8,618 270

Imports from other countries were insignificant except last year when 112 cars valued at $256,559 were imported from Germany; 71 cars valued at $132,701 from France and nine cars valued at $12,451 from Italy. The total value of automotive imports in 1920 was $9,031,589.

Nash Cuts Prices on Complete Line

Reductions Ranging from $150 to $250 Will Become Effective on July 2

KENOSHA, WIS., June 23—The Nash Motors Co. announces a reduction in prices of Nash passenger cars, both six and four cylinder models, ranging from $150 to $250. These prices, effective July 2, are as follows:

6 cylinder	old price	new price
5 passenger touring	$1695	$1545
7 passenger touring	1875	1695
7 passenger sedan	2895	2695
4 passenger coupe	2650	2395
2 passenger roadster	1695	1525
4 cylinder	**old price**	**new price**
5 passenger touring	$1395	$1195
2 passenger roadster	1395	1175
3 passenger coupe	1985	1735
4 passenger sedan	2185	1935

In a statement announcing the price cut, C. W. Nash said the reductions represented lower production costs in the plants at Kenosha and Milwaukee. He added that during the four years prior to last October Nash prices had risen only 31 per cent. Plant economies have been effected by the installation of the latest labor and time saving devices.

HANDLEY CUTS TOURING CAR

KALAMAZOO, MICH., June 22—The Handley-Knight Co. has reduced the price of its seven-passenger touring car from $2,985 to $2,850, making a total reduction of $500 since last November. Prices of the sedan and deluxe models remain unchanged. The company notified its distributors on June 1 that prices which prevailed then would be guaranteed up to Jan. 1.

CADILLAC NOT TO CUT PRICE

DETROIT, June 22—President H. H. Rice of the Cadillac Motor Car Co. denied to-day reports current here that the price of the Cadillac would be cut July 1. "We have said right along there would be no reduction in Cadillac cars this year and that statement stands," said Rice.

MORELAND TRUCK REDUCED

LOS ANGELES, June 22 — Moreland Motor Truck Co. has reduced prices on all models effective to-day. The 1½-ton model is priced at $2,800; 2½-ton, $3,500; 3½-ton, $4,600, and 5-ton, $5,000. The former prices on these models were $3,125, $3,900, $4,975 and $5,350, respectively.

VICTOR INCREASES OUTPUT

SPRINGFIELD, OHIO, June 20 — Starting to-day the Victor Rubber Co. will increase its production from 500 to 700 cord tires per day. "The outlook for business is much better," said H. H. Durr, secretary-treasurer of the company. "Dealers' trade is reported good in practically all sections, but there is a slight slump among the big factories on new cars. Our company sells to dealers and as a result business is good." Durr said that the rubber mat department is rushed with work.

Wilson Assumes Place as Maxwell President

DETROIT, June 21—In assuming his duties as president of the Maxwell Motor Corp., W. R. Wilson declared he welcomed the opportunity presented by his new position for getting a further insight into the automobile business.

"During the period I have been out of direct contact with the automobile industry," he said, "I have watched its development very carefully. I have had a vantage for observation that is in a measure denied those who have been active in it as I have had the benefit of distance in looking at its present problems and its promising future. I feel that the Maxwell offers a wonderful opportunity."

Louisiana Protests High Gasoline Prices

SHREVEPORT, LA., June 20—Automobile dealers and users here are incensed because of the continued high prices of gasoline, when small Texas towns less than 40 miles away are favored with a rate 5c per gallon less. Voicing the sentiments of local automobile dealers and users, George D. Wray, an official of the Shreveport organization, has sent the following telegram to former Lieutenant Governor T. C. Barrett, member of the Constitutional Convention at Baton Rouge:

"Automobile dealers of Shreveport, seriously protest against continued high prices of gasoline in Louisiana. Texas points having no refineries are quoting 18c or lower at filling stations. Price at Shreveport is 23c. Perhaps this is not the business of the Constitutional Convention, but it is a matter which should engage the attention of every citizen of Louisiana who has the best interests of his state at heart. Forty thousand users of gasoline in Louisiana would like to see some action taken before adjournment."

Pierce-Arrow Assets Far Exceed Liabilities

NEW YORK, June 23—The balance sheet as of April 30 of the Pierce-Arrow Motor Car Co. shows quick assets of $20,878,000 and current liabilities of $8,379,000, a ratio of approximately two and one-half of assets to one of liabilities. Directors of the corporation said that the information is made public at this time to refute rumors in Wall Street. Both the common and preferred stock of the corporation were under pressure yesterday, the preferred dropping 5⅝ points to 34 and the common 3½ points to 15⅝.

"The Pierce-Arrow Motor Car Co. is in a sound condition," said the statement. "Of course our business has slumped and the truck business is very poor. We sold 2200 passenger cars last year. Our schedule this year was 1000 passenger cars to June 1. We have sold and shipped 850 of these and we now have orders for 350 cars on our books.

"Our cash on hand, as of this morning, amounts to $1,137,000. Our bank loans are $6,650,000 and our borrowing limit has by no means been reached. Among our quick assets we have listed $17,027,000 as inventory, and cash on hand, and current assets and accounts receivable of $3,851,000. On the other hand, our liabilities are $1,604,000 in bills for raw materials, $125,000 due customers for deposits and $6,650,000 in bank loans."

Rear Bumpers to Make Lower Collision Rate

MILWAUKEE, June 20—Milwaukee automotive dealers have just received advices of additional reductions in collision insurance that will become effective July 1. The Automotive Underwriters' Conference, which for some time has given a 10 per cent reduction in the collision insurance rate for the use of front bumpers, so far as such accessories are approved by the Underwriters' Laboratories of Chicago, will offer an additional 2½ per cent reduction for the use of approved rear bumpers, when the list of such bumpers is ready. The casualty department of the laboratories is now making tests and will issue new list July 1.

Front bumpers have been found unsuitable.

Austin Light "Four" to Appear in Fall

Design Will Follow Specifications of "Twenty"—Coal Shortage Hits Rover

LONDON, June 10 (By Mail)—Design of the new light car which the Austin company will standardize for 1922 is not definitely settled, but it will be of 10 hp. and practically a replica of the Austin "twenty." It will have a 4-cylinder detachable head engine with side valves, three point suspension as unit with four-speed gear set, the latter with central control. Bore and stroke are to be 2 7/8 x 4.

Other details include silent chain for distribution, pump water circulation, fabric disk, universal joints, helical bevels, straight sided frame, tapering front to rear, and semi-elliptic springs Two types of body will be standardized—four-passenger and coupe. The new model will be shown for the first time at the Olympia show in November.

The hearing of the petition of creditors for action on their claims has been adjourned for several months to give the company opportunity to complete its working plans. Operations are continuing under the receivership.

Judgment was entered this week in default of defence against the Austin Motor Co., in the suit of the Eagle Star & British Dominions Insurance Co., holders of all the first mortgage notes of the Austin Co., the value of which is £150,000 and carrying 10 per cent interest. The judge, besides deciding for the Eagle company, directed an account to be taken of what is due to a London bank as holders of the second mortgage debentures.

Limited coal supply, owing to the miners' strike, has compelled the Rover company to reduce its output of the new 8-hp., air-cooled, 2-cylinder runabout. Orders had been received warranting a production of 200 weekly, but this is now cut to one-third of that schedule.

Owing to the national financial tightness the Air Ministry will dispose of the six airships now under its control. These are ready to operate under commercial conditions from a mooring mast. The capital of any company acquiring the ships must be controlled by British shareholders and the Air Ministry must be represented on the board of directors.

Entry of implements for the farm tractor and implement tests to be run in the autumn at Shrewsbury by the Society of Motor Manufacturers and Traders, Inc., has been so large that it has been necessary to obtain special land for their trials. To further encourage a bigger entry list, the closing date was extended to June 30.

PHILIPPINES DOUBLE ROAD WORK

NEW YORK, June 18—Nearly 200 kilometers of new road were completed in 1920 in the Philippine Islands, according to reports received by the Bureau of Foreign and Domestic Commerce showing that the total expenditure of $1,905,645 for public works that year was about $1,100,000 greater than during 1919. Many roads were reconstructed and numerous bridges built. Waterworks and irrigation systems also were gotten under way which are designed to benefit about 300,000 hectares of agricultural land when the projects are completed.

British Dunlop to Make Straight Side Tires

NEW YORK, June 18—News has just reached this country that the Dunlop Rubber Co., the largest tire manufacturing concern in Great Britain, has decided to manufacture straight side tires for passenger cars hereafter. In a recent talk to members of the press the production organizer of the Dunlop company summarized the advantages of the straight side tire as follows:

"The straight side type carries within itself the inextensible edges which resist the outward radial pressure due to inflation of the air tube. The beaded edge type, on the contrary, depends on the proper engagement of the thickened edges with the inturned lip of the rim. The stresses and movement of the cover at this point produce a serious risk of failure by rim cutting.

"The straight side rim provides a wider base for the tire than is possible with the beaded edge type and holds the tire more steadily, prevents roll reducing the tendency to side slip, provides greater air space, and consequently increased cushioning capacity within the tire, and entirely eliminates accidental bursts due to careless fitting.

"The attachment is sound and simple; it is effected without any strenuous levering and stretching of stiff edges into or out of position as is necessary with the beaded edge type. The larger and heavier the tire the more marked the advantage of the straight side type. It is only the lighter weight and greater pliability of the smaller sizes which still permit small beaded edge tires to compete with the straight side type.

"When in position on the rim, no sudden deflation from a cut can cause the straight side tire to leave the rim, and there is no possibility of the tire edges blowing over the flanges. The straight side type of tire has proved the most secure tire for racing work."

TO CLEAR WAREHOUSED STOCKS

NEW YORK, June 18—Preliminary organization of the liquidating corporation to handle and dispose of any unclaimed merchandise in South American customs houses will be undertaken by a committee of eight, among whose members are C. I. McReynolds of the General Motors Acceptance Corp. and S. A. Breese, of the International Harvester Co. The committee was announced by the Argentine-American Chamber of Commerce here and will proceed with the organization plans at once.

METAL MARKETS

MARKET opinion has now been unanimous for several weeks that steel prices must and will be reduced. There has not been and is not now such concord of view as to the time when this generally looked for downward revision of prices will materialize. Still greater disparity of opinion prevails as to the extent which the expected cut in prices will assume. In fact the minds of those who as a rule are qualified by experience and intuition to pass worth while judgment on the impending course of the market are so far apart on this subject that its discussion is eschewed—seemingly by common consent. In seeking to arrive at an estimate of what would constitute a logical reduction in steel prices the consumer is naturally tempted to have recourse to the pig iron market as a plumb line. Eliminating from consideration the period of 1916, when the pig iron market in its upward climb was for a brief spell on the same basis as it is to-day, prevailing levels put the market back to where it was in September, 1907. In the latter month billets sold at around $29, compared with the present quotation of $37. The average price for black sheets, No. 28 gage, in 1907 was 2.50c., compared with the present nominal quotation of 4c. If the forthcoming cut in steel prices is to re-establish the conditions that prevailed in 1907, i. e., the ratio which then prevailed between pig iron and steel prices, it would have to range approximately from 25 to 37½ per cent. Even if the fervently prayed for revival in demand should exceed the fondest expectations, the steel market of 1921 and 1922 is bound to be in more precarious a condition than was that of 1907, for the simple reason that capacity is so much greater. So that taking for granted as preliminaries to any reduction in steel prices a satisfactory pruning of freight rates and further paring of wages, a 25 per cent cut in prices when the cut does materialize, would be consonant with conditions in general and with those in the pig iron market in particular. It is, however, not at all improbable that by the time revision in steel prices materializes, the pig iron market will have rebounded from its present low levels. At best it is never an efficient instrument for measuring the future trend of steel prices. The probabilities are that the powers that be will permit the steel market to find its own low levels in the present depression, resorting to more and more shut-downs to meet the situation, thus facilitating the downward readjustment of wage schedules. Constructive action with reference to prices will be deferred until sufficient demand has accumulated to make revision of prices yield immediate results in the form of orders.

Pig Iron.—Inquiry by the Ford Motor Co. for 60,000 tons of ore is not looked upon as presaging contracts for that tonnage. Experience throughout 1921 has convinced the iron ore and pig iron trade that there is a wide gulf separating inquiries from actual orders and sales. Buyers, for the time being, can make their own prices for foundry and malleable pig.

Steel.—Virtually no new business is forthcoming from the automotive industries. Cold-rolled strip steel and steel bars are moving in less than carload lots, if at all. It is stated that the Sharon plant of the Savage Arms Corporation, which has closed for repairs, will resume as soon as these are completed, to continue production of frames for the Dort Automobile Co. Spasmodical sales of sheets in retail tonnages are the order of the day.

FINANCIAL NOTES

Studebaker Corp. earnings for the second quarter of 1921 which ends June 30, are $8 a share. The quarter is the best in the history of the company. Earnings for the first quarter were slightly better than $3, which means that the $7 dividend for the year has been earned with a margin of $4.

Hendee Mfg. Co. has reduced the total of its bank loans to $240,000, a reduction of $610,000 since 1920. Accounts payable have also been reduced to $262,000, a reduction of about $600,000 this year.

Elgin Motor Car Corp. will offer $500,000 serial debenture 8 per cent notes to stockholders at par. They will mature in one year $100,000; in two years $150,000, and in three years $250,000.

Sayers & Scoville Co., Cincinnati, has declared the regular quarterly dividends of 1½ per cent on both preferred and common stock, payable July 1.

American Bosch Magneto Corp. has passed the quarterly dividend due at this time. The company had been paying at the rate of $1.25 a share.

Reo Motor Car Co. has declared the regular quarterly dividend of 2 1-5 per cent on the common stock, payable July 1.

Stutz Motor Car Co. directors were all re-elected at the annual meeting of the company.

INDUSTRIAL NOTES

Neskov-Mumperow Motor Car Co., St. Louis, has entered the storage battery manufacturing field, producing the Hy-Volt battery. Harold Dickelman, who has been associated with several local battery concerns, has been appointed manager of the new branch of the business. The new battery is sold under a two-year guarantee.

International India Rubber Corp., South Bend, Ind., is now the Odell Rubber Co., the change being now officially announced by the directors of the company. The business of the company will not be changed in any detail. New offices and warerooms at the plant will be completed by July 1.

Ward-Boucher Specialty Mfg. Co., Minneapolis, has been incorporated to manufacture an auto signal which operates from a button on the steering post an arrow at either side of the windshield to give a traffic warning.

Cutler Auto Radiator Co., Inc., Camden, N. J., has been incorporated with $125,000 capital stock, to manufacture a new type of automobile radiator having a removable and floating cooling unit.

Soss Mfg. Co., Brooklyn, N. Y., manufacturers of Soss automobile hardware, has completed an addition to its factory, extending the company's efficient manufacturing facilities.

A. H. Petersen Mfg. Co., Milwaukee, has discontinued its tool and die department to concentrate on the manufacture of portable elecric drills and other automotive devices.

Ford Motor Co. may acquire three plants of the government nitrate works at Sheffield, Ala. An inspection tour of the plants has been made by Henry Ford with a view to discovering their practicability for automotive manufacturing.

Lafayette Motors Corp., Indianapolis, has turned over its entire building and housing project to the real estate department of one of the Indianapolis banks.

Automatic Oil Indicator Co., Newark, has been organized to manufacture oil indicating apparatus and other automotive equipment.

Gill Mfg. Co., Chicago, manufacturer of piston rings, reports a sales increase of 45 per cent for the first four months of 1921.

Philadelphia Rubber Works at Buffalo have been sold to the Du Pont Fibersilk Co.

Trustee Is Nominated for Seiberling Property

AKRON, June 20—An arrangement has been entered into by F. A. Seiberling, former Goodyear president, and various of his creditors, whereby it is agreed that a corporation to be known as the Prudential Securities & Realty Co. will assume trusteeship over Seiberling's personal assets and liabilities and will manage his property at least temporarily.

Seiberling's assets, not including his $5,000,000 mansion Stan Hywet Hall, which is said to be in his wife's name, are listed at $10,136,570 and his total liabilities are $6,700,000.

Under the agreement creditors consent to extension of maturity of debts and claims against Seiberling.

Seiberling's largest holdings include Goodyear common and preferred stock, $2,535,430; raw rubber $500,000; Ladysmith Smelting Corp., $1,681,750; Ohio Savings & Trust Co., $144,500; Whitman & Barnes Co., $203,500; Hotel Cleveland Co., $45,000; Blackstone & Fairlawn Heights property, $2,286,475; Morris Plan Bank of Akron, $18,000; old Seiberling home on East Market Street, $82,048; one-half interest in the Delaware building, and appraised value of realty and other assets, $943,686; equity in Central office building of Akron, $160,000; Summit County farm land, $378,202.

TO SELL IMMEL JULY 9.

COLUMBUS, June 18—R. H. Schryver, president of the Citizen's Bank & Trust Co., and receiver for the Immel Co., manufacturers of closed bodies, has been authorized to sell the physical property at public auction July 9. The court issued the court order upon application of the receiver, who believes it is a good time to sell. The preferred stockholders of the company have organized and will be a bidder for the property, which consists of three separate plants and some separate land. The entire property is appraised at $253,200. All materials on hand will be offered for sale and are separate from the plants. No appraisement of the materials has been announced.

RAILROAD DISCONTINUES

WASHINGTON, June 20—Motor vehicle competition is given as the cause for the abandonment by the Ocean Shore Railroad of its lines in California, extending from San Francisco to Tunitas Glen, and from Santa Cruz to Swanton. Authority for abandoning the road was granted to-day by the Interstate Commerce Commission. A lumbering and agricultural territory was served by the carrier.

BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, June 23—The local money market was little affected last week by the announcement of the New York Federal Reserve Bank that it had cut its discount rate on commercial paper from 6½ per cent to 6 per cent, making the discount rate now 6 per cent for all classes of bills. The whole financial community as a matter of fact was concerned more with the continued precipitate decline in the stock market, the irregularity and dullness of the bond market, and the unsteadiness of the foreign exchanges. In addition to these unfavorable factors, cotton prices reached the lowest level for several years, and the grain markets were under pressure.

In spite of marked improvement in the great majority of items in the Federal Reserve System's midweek statement, the reserve ratio declined last week from 58.3 per cent to 56.8 per cent. Gold reserves increased $14,896,000, and total reserves $23,078,000. Total bills on hand declined $204,981,000, largely as a result of a $188,680,000 reduction in bills discounted. In spite of the reduction in bills on hand, total earning assets increased $93,261,000 as a result of large government borrowings shown on the statement by a $295,861,000 increase in certificates of indebtedness. Federal Reserve note circulation declined $36,288,000, while deposits increased $194,170,000, which accounted for the lower reserve ratio.

Commercial failures for the month of May show a substantial decline in the number of failures, but a marked increase in the total liabilities involved. The number of failures at 1356, was 131 less than in the previous month, but compares with 547 in May, 1920. Liabilities involved amounted to $57,066,471—the high record for the month of May. In May of the preceding year, liabilities involved for the 547 failures amounted to only $10,826,277. For the first five months of the current year, the total number of failures amounted to 7713, which was exceeded as recently as 1916, but the total liabilities for the five months at $276,032,229 are by far the high record for all time for the five months. The liabilities involved in commercial failures for the first five months of 1920 amounted to only $53,752,911.

U. S. BUYS RUBBER FOR YEAR

NEW YORK, June 18—The United States Rubber Co. is taking advantage of the current price of 16 cents to 17 cents for crude rubber and is laying in a year's supply. Rubber producers assert that the actual cost of producing crude rubber is about 32 cents and that growers are losing money at the current level. The United States Rubber Co. will leave the trees on its own plantations untapped for a year or so, or as long as rubber can be purchased in the open market cheaper than it can be produced.

MEN OF THE INDUSTRY

C. M. Alexander has been appointed manager of the Houston plant of the Ford Motor Co., succeeding W. M. MacDonald, who has resigned. Alexander has been with the Ford Motor Co. in Houston for the last five years and has been assistant manager most of that time. MacDonald will be tendered a Ford agency at some point it is understood. With the early occupancy of the newly-built addition to the plant of the Ford Motor Co., Houston will have the largest Ford assembling plant in any of the southern states, officials state. At the present time the plant is turning out seventy cars per day, which will be increased to more than one hundred as soon as the installation in the new addition is complete.

George J. Fix has resigned as manager of the New Orleans branch of the Bearings Service Co. and will establish in Dallas, Texas on July 1 a sales agency representing the Baldwin Chain & Manufacturing Co. and the Joyce Auto Products Co., covering the State of Texas. Fix was formerly connected with the Maxwell Motor Co., in charge of service for the southwest.

John N. Willys has accepted the appointment on a committee which will organize throughout the country branches of the "Sell Now League." The purpose of the organization is to stabilize economic conditions by selling "now" in selected markets. Willys believes such a campaign is absolutely necessary to hasten the return of normal conditions.

L. O. Haskins, vice-president and general manager of the Powrlok Co. of Cleveland, has become associated with the Seelye & Brown Advertising Agency, Detroit. He was formerly with the O. & S. Bearing Co., Detroit, and later with the Willys interests. He is a member of the Society of Automotive Engineers.

Nelson B. Nelson, formerly superintendent and chief engineer for the Kardell Tractor & Truck Co., St. Louis, and for the past twelve years connected with tractor engineering, has become associated with the New Departure Mfg. Co., and will have charge of engineering at its Chicago office.

A. E. Fauts, who for the past two years has been in Europe in the interests of the Garford Motor Truck Co., has returned to New York, where he will confer with officials of the company on European truck markets and the future policies of the company in that field.

C. E. Wagner, export manager of the Miller Rubber Co., is attending the International Trade Conference in Mexico City. In addition to his representation of the company, he is also representing the Cleveland Chamber of Commerce and the Akron Chamber of Commerce.

Harry W. Anderson has been appointed general sales manager of the Duesenberg Automobile & Motors Co., Inc., Indianapolis. Until recently Anderson was sales manager of the Templar Motors Corp., Cleveland. He will assume his duties with Duesenberg at once.

Ernest M. Orr, plant manager of the Jacox Steering Gear plant of the Saginaw Products Co., has been made assistant to George H. Hannum, president and general manager of the Oakland Motor Car Co. Orr has been associated with Hannum since 1906.

J. Parker B. Fiske has resigned as president and general manager of the Frigidaire Corp., a General Motors Corp. subsidiary. The Frigidaire interests are being merged into the Delco Light Co. and will be under the direction of R. H. Grant, general manager.

M. E. Lyle has been elected a vice-president of the Terminal Engineering Co., Inc., New York. M. E. Peck has been elected secretary and assistant treasurer. J. F. McGonigal and J. H. Potter have joined the engineering staff of the company.

Harry Gardner has retired as manager of passenger car sales for the Packard Motor Car Co. He has not decided upon his plans for the future. Gardner formerly was secretary of the New York Automobile Dealers' Association.

John J. Plath has been made director of sales of the Maxwell Motor Sales Corp., and E. W. Clark, director of sales of the Chalmers Motor Car Corp., according to announcement by A. W. Barker, general sales manager.

George H. Daugherty has been elected a vice-president of Johnson, Read & Co., advertising agents of Chicago. Daugherty has specialized with this company on car, truck and tractor advertising.

J. A. Callahan, vice-president, in charge of production of the Martin-Parry Corp., has been elected vice-president and general manager of the corporation at the annual meeting of the board of directors.

L. J. Ollier, vice-president of the Studebaker Corp. of America, has returned from a trip to Europe, where he has made an investigation of trade conditions.

J. H. Appleby has been appointed a motorcycle tire representative by the Firestone Tire & Rubber Co.

Revere Reorganization Opposed by Stockowner

INDIANAPOLIS, June 20—An order was issued by Judge Geiger in Federal Court yesterday in the suit filed by John B. Porter, of Buffalo, N. Y., a stockholder of the Revere Motor Car Corp., who is seeking to prevent reorgnization.

The order directed officers of the Revere company and the Citizens Loan & Trust Co. of Logansport, Ind., receivers of the corporation, to appear in Federal Court June 22 and show cause why a temporary restraining order should not be issued against them preventing the reorganization or sale of the corporation. The bill also asks for an accounting, alleging that the corporation should have more than $1,500,000 in visible assets, instead of being insolvent.

CHINA DEVELOPS CAR LINES

WASHINGTON, June 17—Progress is being made in China in the way of establishing motor car highways, declares Consul John K. Davis, Nanking, China, in a report which has been received by the Bureau of Foreign and Domestic Commerce. Previous reference has been made by Consul Davis to the establishment of a motor car service between Pochow, Anhwei, in the Nanking consular district, and Techow, Honan, and he reports four other similar services are either in the process of being established or are definitely planned. It is stated that American exporters desirous of cultivating the automobile market in the Nanking consular district, said to be rapidly growing, can do so to the best advantage by establishing branches or agreements in Shanghai.

Receivers Are Named for Ideal Tire Company

CLEVELAND, June 20—On the application of Edward Maurer of New York, who furnished the company with much of its supply of fabric, Federal Judge D. C. Westenhaver has appointed Newton D. Baker, former secretary of war, and Edward L. Griffith, well known business man and financier, receivers for the Ideal Tire and Rubber Co.

The assets of the company are placed at $1,660,000 and the bills payable amount to $700,000, most of which is due on materials bought at prices far above the level of to-day. A short time ago, it was announced that the company owed but $114,000 exclusive of the money due for materials and that approximately $500,000 was owing on rubber fabric that was purchased at $3.10 a pound. The price now is about 80 cents a pound.

The factory is employing approximately 200 men and women now and the receivers will continue to produce tires, for which there has been a good demand. The corporation was organized in 1917 with a capital of $5,000,000. A factory was built and production started early after the organization.

Seek $10,000,000 for New Mexican Highway

SAN ANTONIO, TEXAS, June 20—The Highway Propaganda Committee of the Meridian Highway Association, has left Laredo, Tex., for an automobile tour to Mexico City to further the proposed Mexican highway through the States of Tamaulipas, Neuve Leon, Coahuila, San Luis Potosi, Guanajuato, Queretaro, Hidalgo and Mexico. The road, which will be over 1000 miles in length, will cost in excess of $10,000,000 Mexican currency.

The road party will endeavor to finance the road. It is proposed that the Mexican government furnish 40 per cent of the cost of construction and assess an automobile tax which will bring in about $2,500,000. The remainder, about $3,500,000, is to be raised by subscriptions along the run.

MINNEAPOLIS TO HAVE SHOW

CHICAGO, June 20—A tractor show will be held during the coming winter in Minneapolis by the National Implement & Vehicle Association under the Show and Demonstration Committee, headed by Chairman J. G. Bartholomew. This committee has also agreed to have a tractor show during the winter at some point in the Southwest, either at Kansas City or another place where suitable arrangements can be made. Last winter the tractor show was held at Columbus, Ohio.

Calendar

SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

RACES

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Commission to Clarify Aeronautical Situation

WASHINGTON, June 21—As a step toward clarifying the aeronautical situation, Herbert Hoover, Secretary of Commerce, has agreed to appoint an Aviation Consulting Commission which will present for the consideration of President Harding a policy for the advancement of aeronautics in this country. This action followed a petition to the President by 50 executives representing civilian aviation organizations throughout the country.

The petitioners included Glenn H. Curtiss, Glenn L. Martin and C. F. Redden, and such organizations as the Aero Club of America, the Manufacturers' Aircraft Association, the National Aircraft Underwriters' Association, the Society of Automotive Engineers and the National Advisory Committee for Aeronautics. They asked for a commission to study and outline a report dealing with America's future in the air, a general policy for the Government to follow in developing civilian aviation, suggestions for air routes and termini and recommendations for aerial laws.

Borah Offers Measure to Abolish Air Board

WASHINGTON, June 18 — Senator Borah of Idaho, has introduced a joint resolution which would abolish the organization known as the National Advisory Committee for Aeronautics, and transfer its property and duties to existing governmental agencies. It is expected that a fight will develop when this measure is reported from the Committee on Military Affairs, for the Advisory Committee for Aeronautics has functioned as an independent agency.

The joint resolution provides that in the abolition of the committee, the technical duties that have heretofore been carried on by the body, or that have heretofore by law been charged to the body, be transferred to the Department of Commerce, to be carried out by the Bureau of Standards. It is also provided that the technical equipment now in the possession of the National Advisory Committee for Aeronautics be transferred to the Department of Commerce, Bureau of Standards. The duties of this committee as relate to its advisory capacity on the subject of aeronautics would be transferred to the War Council, as created by the national defense act approved June 3, 1916, as amended by acts subsequent to June 3, 1916, to and including the act of June 4, 1920.

Kerosene Carburetor Is Demonstrated Here

NEW YORK, June 17—Mr. Mandahl, a Swedish inventor, has arrived in this country with samples of the Kjellberg kerosene carburetor, a device adaptable to use on trucks, tractors and other automotive vehicles. He has fitted the carburetor to a Republic truck and is giving demonstrations with same.

The general principle of the device is that a mixture of kerosene spray and air is formed in the mixing chamber and the kerosene mist is then vaporized while passing through a copper pipe surrounded by an exhaust heating chamber. This stream of over-rich mixture is later diluted with additional air entering through a supplementary air valve, passes through a throttle valve and through a change-over valve to the engine. By means of the change-over valve the engine can be connected to a gasoline carburetor for starting and for heating up. A full description and a diagrammatic illustration of the carburetor appeared in the Sept 16, 1920, issue of AUTOMOTIVE INDUSTRIES.

FIX BRITISH SHOW DETAILS

LONDON, June 10 (By Mail)—The big British automobile show will be held simultaneously at Olympia and White City from Nov. 3 to 12. The truck show will be held Oct. 13 to 22. Arrangements have been made whereby accessory exhibitors who have space in the gallery at Olympia for the truck show may retain the same space for the passenger car exhibit. No changes in prices will be permitted while the shows are in progress. Tractors will be admitted to the truck show if they are provided with means for traveling the roads and are licensed for that purpose.

Transportation Situation Shows Gains for Trucks

WASHINGTON, June 17—One of the outstanding developments of the present transportation situation has been the growth of the automobile truck in short hauls, making it a formidable competitor of the steel rail, according to Archer Wall Douglas, chairman of the committee on statistics of the Chamber of Commerce of the United States, in his semi-annual report on business conditions. He also stressed the fact that there has been some increase in the output of automobiles, notably in certain localities. He finds that purchasing power is still high, despite many untoward conditions and that there is still money to be spent where bargain prices are in evidence. The committee advises American business that there is no immediate return to prosperity in sight, at least until the termination of the harvest season.

Gasoline Railway Cars Keeps Operation Low

LOUISVILLE, June 18—The Carrollton & Worthville Railroad Co., operating a strip of road ten miles long, is the only company operating in Kentucky which has not raised passenger fares since the depression period began.

This company solved the problem by shelving its steam locomotives and substituting gasoline motor vehicles. The cars, have attracted the attention of short line railroad companies as far south as Louisiana and as far west as New Mexico. Automobile manufacturers have studied them with a view to their practicability for adaptation to street car service.

Operation of one of these cars for one round trip costs $2, counting repairs, labor, gas, oils and depreciation. The trip with a steam locomotive costs from $15 to $18.

PERFECTION SUIT DROPPED

WILMINGTON, Del., June 20.—The receivership proceedings brought in the United States Court here against the Perfection Tire & Rubber Co. of Detroit, by the Southwark Foundry & Machine Co. of Philadelphia, have been dropped.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV. NEW YORK—THURSDAY, JUNE 30, 1921 No. 26

Industry's Present Opportunity for Public Service

We recently have had lessons in what government can cost. Now the demand is for a more economical and a more efficient government. This can come about only as economy and efficiency are put into government by those who know how.

By Clyde Jennings

DURING the war the automotive industry sent many men to Washington and into similar public service because they were needed.

It was this public service on the part of the men of the industry that has gained for the industry, since the war, an instant hearing when it has asked opportunity to present its side of any controversy.

Now comes an opportunity for a similar service. The present crisis is not, perhaps, as acute as the former opportunity. Then men were needed to avert the calamity of violence that threatened from the other side of the world. Public service then was self-preservation for our institutions and our country.

At this time the opportunity for public service is chiefly to hasten the period when American business will come back to its own; to dislodge the bureaucracy that has become more strongly enthroned in our Government during the war; to put our Government on a modern business basis, compatible with the change that has been brought about in business during the last decade; to assist Congress in resisting those who have little respect for the greatest benefit of the public; to end the period of public extravagance; to carry out the tax program suggested by the National Automobile Chamber of Commerce and practically adopted by the administration.

The meat of the N. A. C. C. tax suggestion was contained in this one sentence that stood at the head of its program:

"Reduce ordinary expenses from war standards to sane, normal standard at once."

The Chamber of Commerce of the United States had for a slogan at its annual meeting:

More Business in Government.
Less Government (management) in Business.

To which Herbert Hoover added this line:

Better Government assistance in business.

A proper response of the chamber would have been:

Better Business Assistance to Government.

The present administration is working to this end, and this offers the present opportunity for public service. Very prominent in the program are two points, and both of these must have co-operation from business if benefit is to be gained. Here are the two most prominent:

The Budget Commission.
The new Department of Commerce.

The appointment of Maj. Gen. Charles G. Dawes, the Chicago banker and once Comptroller of Currency, as Director of the Budget is evidence that the

administration is in earnest in this economy move. General Dawes has performed two admirable feats of public service for the Harding administration, hence the appointment. He it was who went to Washington and was outspoken in defense of the earnest men who made some mistakes but did the best they knew to win the war. His outspokenness in this cause brought cheer to every dollar-a-year man who was threatened with a technical inquiry into his acts.

Hardly had the air been cleared from his lurid testimony on this subject when he was called back to conduct an inquiry into the mistreatment of invalid soldiers. This was supposed to be a six months' job. But Dawes surprised the country by granting that mistakes had been made, and in two days he had drawn a report of a reasonable system of management of this work and going home, putting the entire situation up to those whose responsibility it is to carry out this work.

Now this same Dawes is called back to inquire into the methods and systems of the Government and see if they are economical and efficient. He says this is a big task and that he must have much more assistance than can be employed with the money Congress has placed at his disposal. He proposes to work fast and to bring about such changes as may be wise or necessary within six months. He says that government is a big business, and the only men competent to adjust a big business enterprise are men who have had experience in big business. So he proposes to call to Washington many big business men who will be placed in the departments there to see if these departments, bureaus or whatnot are efficient from a business standpoint.

To answer such a call will doubtless disturb many a business man's plans. But government is much like a trade association: In the main you get out of it only in proportion as you put into it. Business men with one accord are saying that our Government is not efficient. They have demanded changes. Dawes is going to say to them:

You have been uttering destructive criticism, now we ask you for constructive assistance.

If business does not answer the Dawes call, it will never again be able to ask with reason for an adjustment of government to a new basis.

The response of the automotive industry and other industries that are crying out against high taxes will be the measure of the answer to that call.

The need for public service is very great in this crisis. The administration has neatly put industry on the defensive. We have faith that industry will not fail.

The New Department of Commerce

It has long been an axiom that a trade association benefited the member only in relation to what he puts into it.

The same is true of government. Secretary Hoover is offering to industry a very great opportunity to put much into government and in return draw much out of it. Hoover's connection with the engineering service, world adjustment of supplies and similar big enterprises are too well known to need comment here. His last public service before entering the Department of Commerce was at the head of the Survey for the Elimination of Waste. This movement is doubtless familiar to most industrial leaders, although the results have not as yet been made public in a definite form.

It is evident that in assuming his duties as Secretary of Commerce, Hoover carried with him many of his ideas on industrial waste. His present effort is to make this country a more efficient industrial unit, and to this end he is lending his assistance toward making government more efficient and to making industry more efficient.

It is Hoover's idea that business needs some sign-posts and traffic regulations, so that the movement of business can be more uniform and some of the sudden bursts of speed that serve only to exhaust the particular industry can be eliminated.

Business, as Hoover views it, is an interdependent structure. It has the common purpose of serving the population of the world well, or it cannot be at its best. Waste, be it in materials, idleness of plant or employee, is a handicap on everything in the world. Waste in any part of the world is important to all business.

The automotive industry cannot flourish without assistance from other industries, according to the Hoover view, and in turn the automotive industry greatly aids all other industries. This is true not only in actual turnover of business, but in the information that the industry may have gathered from its own peculiar field.

Industry needs to become better acquainted, so that it may better appreciate its interdependence and better help itself as a whole. It needs to better balance its production with sales prospects, and sales prospects depend entirely upon buying power. Buying power is at its best only when all industry is going with a considerable degree of efficiency. Each industry is too inclined to "go it alone."

This condition can be greatly remedied by acquaintance and a mutual program. Hoover sees in the ideal Government Bureau of Commerce just such an agency, and he is working toward this end with the material that he can avail himself of. His present efforts are chiefly toward a gathering of the material that will serve as sign-posts and, when properly appreciated, as traffic regulations. The over- or under-production is at present probably the greatest waste in industry. That probably is why the first step has been taken toward a gathering of industrial activities to present a complete picture of index of business.

This accomplished, the other points of the program will become workable. Too few of us appreciate standardization in the big way. The first idea always is that all automobiles or stockings are to be made by the same pattern and of the same material. Secretary Hoover in his vision of possibilities sees a much larger meaning for standardization. It has not been harmful to the hosiery business that stockings have been standardized as to size, so that one firm's size 9 was the same as another firm's size 9. It has been helpful. The standardization that has been accomplished within the automotive industry has been helpful and it may be possible that this standardization can be carried on between industries in many particulars for better production.

A very great waste exists to-day because of idleness of plant equipment. It is entirely possible that, with better equipment, those industries that are seasonal can be brought to the aid of other seasonal industries, and a steadier use of equipment and employment brought about.

It is entirely obvious, of course, that a government survey of buying power in a foreign country can be made available to all industries much cheaper than a similar survey by each unit in each industry. Such a survey would indicate whether there was necessity for a survey of a particular unit for its own needs.

Secretary Hoover is going to ask much of industry. It will be a public service to join his efforts, and to assist him in making his plan efficient and equitable.

If we can join these efforts to make our Government efficient and helpful, we will get that much more out of it. If industry puts more into government, it will matter much less what government costs.

Analysis of the Recent Horse-Tractor Work Cost Report

It appears to be extremely difficult to get down to actual facts on what it costs to do work on the farm with a tractor. A recent comparison of horse and tractor cost comes nearer the point than many previous reports.

By David Beecroft

MANY misleading bits of information on what a tractor can do on the farm and how it compares in capacity for work and cost of work are partly corrected in a preliminary report on an investigation of tractor and horse work on 286 farms in Ohio, Indiana and Illinois, conducted by the Bureau of Farm Management and Economics of the Department of Agriculture, the investigations being made by a series of investigators who visited these 286 farms in the latter part of 1920. The Department of Agriculture was assisted in the work by a horse association known as the Bureau of Animal Industry and as such was sponsored by a horse organization rather than by tractor manufacturers. Having originated under what might be designated as horse auspices it can scarcely be considered favorably to tractor farming, but yet the result is generally highly complimentary to the tractor.

During the year covered by the investigation on the 286 farms on which horses and tractors were used, the report shows that the cost of farming by tractor was no greater than the cost by horses. This really means a cheaper cost for tractors, for as the preliminary report of the Department of Agriculture says, "any saving in man labor costs, any gain due to getting a larger amount of work done in a given time, and any other advantage connected with the use of tractors, which cannot be measured directly in dollars and cents, might be considered clear profit."

It has always been considered that a good way for a farmer to get advantages of the tractor on farming is the conservation of man power due to the short time in which a tractor will accomplish a given unit of work, as compared with the time needed by horses. Still another tractor advantage of importance, has been the ability to do the farm work when it best can be done and the greater crop yield due to this, as compared with the longer time needed by the horse. Big tractor farmers have always advanced this as the strongest reason for the tractor. This has appealed to them more than the cost per acre to do the work by tractors as compared with horses.

The government report shows that on the 286 farms using tractors, the tractor does the work of 2.1 horses on an average throughout the year. On these farms the tractors averaged only 30.8 full days' work per year; but the old tradition that the horse works 300 days in the year on the farm was exploded. The horses on these 286 farms averaged 68.6 full days' work per year. The horse is far from working 300 days per year. There is not work for him all the time and if there were he could not stand it the year round.

The report shows that in 1920 the cost of plowing by horse was higher per acre than by tractor. Here are the figures:

Plowing cost per acre, 2-plow tractor	$2.20
Plowing cost per acre, 3-plow tractor	2.20
Plowing cost per acre, horses	2.90

Here the report adds that in 1921 with reduced cost of horse feed the cost per acre of plowing by horses would be $1.90, adding that to the cost of farming by horses has reduced much more in the past year than the cost of farming by tractor. The report makes an effort to show what reduction in cost has been made by tractors due to reduced tractor prices and lower fuel prices.

In such other farm operations as disking and grain cutting the costs by tractor and horse are remarkably close. Here they are:

Disking, tractor, cost per acre	$0.67
Disking, horse, cost per acre	0.64
Grain cutting, tractor, cost per acre	0.67
Grain cutting, horse, cost per acre	0.59

Some light on the cost of keeping horses per year is shed by the report which states that on the 286 farms the average cost of keeping a horse per year is $159. This cost includes charge for feed, shoeing, veterinary, housing, interest at 6 per cent on investment and depreciation. It also gives the horse a credit of $15 per year for manure. The feed for the horse averaged $134 per year alone. Again the report apparently endeavoring to favor the horse estimates that based on March, 1921, prices the cost of feed per horse for 1 year would be about $80, but no deduction as to reduced tractor cost has been made. The average farm cost for horse labor per year on the 286 farms was $1,076. The cost of a horse per day is $2.43 for each day it works based on 68.6 days' work per year.

Some side lights on the long mooted question as to whether a farmer can sell some of his horses when he purchases a tractor are given in the report from the 286 farms. On 172 of the farms there was a reduction of 2.2 horses per farm. A still further analysis of these 172 farms reveals the following:

Farmers who did not reduce horses	44
Farmers who reduced by 1 or 2 horses	62
Farmers who reduced by 3 or 4 horses	43
Farmers who reduced over 4 horses	23

This is a definite answer to the question and the fact that a horse averages only 68.6 days' work per year on the 286 farms leads to the conviction that quite a few more horses could be disposed of if the farmer analyzed the situation as carefully as he might. Before these 286 farmers purchased tractors they had 1 horse to every 27.6 acres and after they had tractors they averaged 1

horse to every 37.9 acres. That there is a very great surplus of work horses on the average farm is plain by the fact that on 143 of the 286 farms all of the horses were not used for any one operation on the farm, there was always a reserve of horses.

Some useful cost figures on tractor operation are covered in the report. The 286 farmers estimated the life of the tractor at 6.7 years. To operate a two-plow tractor per day costs $12.65, and a three-plow tractor $17.75.

In fuel consumption while the kind of fuel used is not given in the report quantities are, and for different farm work the fuel consumption per day is:

Plowing 2-plow tractors	18 gallons
Plowing 3-plow tractors	23 gallons
Hay-loading, 2-plow tractors	11 gallons
Hay-loading, 3-plow tractors	15 gallons
Fuel per acre for plowing 2-plow tractor	2.8 gallons
Fuel per acre for plowing 3-plow tractor	2.7 gallons

The capacity of these tractors per day for different works are as follows:

Plowing 2-plow tractor	6.6 acres
Plowing 3-plow tractor	8.6 acres

The measure of work done by the tractors on the 286 farms covered in the report varied according to the kind of work, naturally the hardest job plowing being largely done by the tractor. Average percentages for all farms:

Plowing (by tractor)	85 per cent
Disking (by tractor)	73 per cent
Harrowing, etc.	43 per cent
Grain cutting	41 per cent
Haying	15 per cent

The volume of tractor sales in a given territory is highly dependent on the acreage of farms in the territory, and the type of tractor is also influenced by this fact. Here are the figures:

2-plow tractors	174 farms
3-plow tractors	104 farms
1-plow tractors	1 farm
4-plow tractors	6 farms
5-plow tractors	1 farm
Total	286 farms

The 286 farms averaged 258 acres, which is larger than the average of farms in these three States and the two-plow tractor was used on 75 per cent of farms under 160 acres and on 53 per cent of farms 160 acres or over.

The tractors were not all new, several having been used over three years and others as follows:

One year or over	106 tractors
One and one-half or two years	100 tractors
Two and one-half or three years	49 tractors
Over three years	31 tractors
Total	286 tractors

With these figures in mind the repair cost per year may be considered. The repair cost per year on the two-plow tractor was $39 and was the same on the three-plow tractor. The two-plow and three-plow tractors were out of commission only two days per year on the average when they were needed. Annual depreciation of the two-plow tractor is put at $164 and on the three-plow tractor $217.

It is questionable if tractors on these farms are used as much as they might be. There is always considerable belt work for tractors, but the report shows them used very little for such. The big job is what is called drawbar work, that is, pulling some implement, such as plow, disk, self-binder, hay-loader, etc. Here is an analysis showing averages on the 286 farms:

Drawbar work	23.5 days
Belt work	2.7 days
Custom work	4.6 days
Total	30.8 days

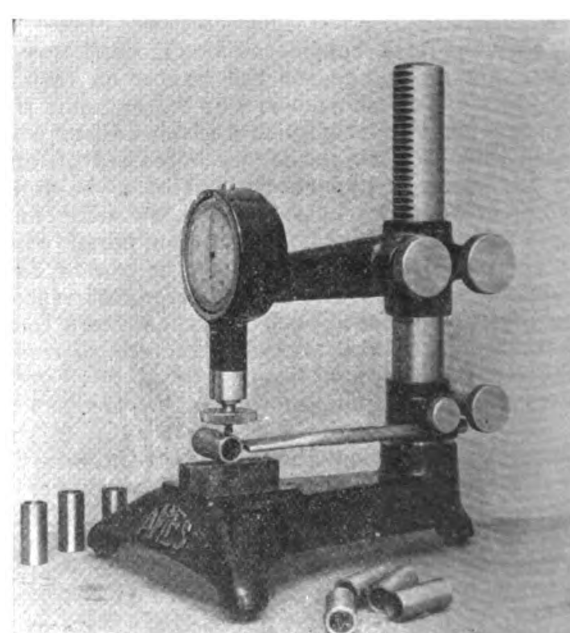
The report contains a few very useful observations on the possibility of farmers reducing cost of doing work by horses and also by tractors. It says: "Repair costs and fuel consumption of the tractors could in many cases have been reduced. The fact that on 20 of the 286 farms the work horses did less than 40 days' work per head per year indicates that on some farms there are still more work stock than needed."

A New Dial Comparator

THE Ames dial comparator, a new instrument herewith illustrated, is intended for use in the shop on production as well as in the inspection department. All parts of the instrument are protected from dust and all bearing surfaces are hardened and ground. The gage is designed for use on bushings, pins, shafts, plates and similar parts. Its advantage over the micrometer is that the personal element is eliminated, the operation of gaging being controlled by a spring. The dial is 1⅞ in. in diameter, giving 0.00005-in. readings direct as 1/16-in. on the dial, thereby enabling readings of .00025 in. to be made with ease.

In using the gage the clamp is loosened and the arm supporting the dial is raised or lowered by the knurled nut until the contact point touches the work or standard. The clamp is then tightened and the hand of the gage brought to 0 by turning the adjusting screw above it right or left. The gage has a travel of ¼ in., so that when set to a 0.500 in. standard it will measure from 0.500 in. to 0.750 in., making it handy on shafts, bushings, etc., of more than one diameter.

A stop is furnished for revolving work against, for out of roundness, etc. The gage is furnished with two hardened and ground anvils, ½ x 2 in. and 2 x 2-in. scored. It stands 10½ in. high and weighs 10 lbs.



The Ames Dial Comparator

An American Built Light Car

Designed along European lines for production in this country. Chassis has 100 in. wheel base, 50 in. tread, and weighs only 850 lbs. Adjustable steering gear and propeller shaft brake among the novel features.

By Herbert Chase

ADMIRERS of British and other European light cars have often expressed the hope that a car of similar design and proportions would be built in this country. Some efforts in that direction have indeed been made but have either failed or the design has been modified to meet the demands of the American public or other domestic factors, notably the competition of cars produced in quantity at a lower price. The Moller Motor Co. is attacking the problem from another angle by the production by American methods of a light car intended not primarily for domestic, but for European consumption. Cars will be marketed in this country, but the present intention is to export the bulk of the cars produced, and not to produce large quantities, probably about 300 chassis the first year.

The chassis, illustrated herewith, has a 100 in. wheelbase, 50 in. tread and weighs only 850 lb. The total weight with two seater body is said to be approximately 1100 lb. The engine has four cylinders of 2¾ in. bore cast in block with detachable L-head. The stroke is 4 in. The crankshaft has three white metal bearings. The front bearing is 2 in., center bearing 1¼ in. and rear bearing 2¾ in. long. The camshaft is also carried in three bearings. It is driven by Whitney chain and an idler is provided to take up the slack in the chain, this adjustment being made by turning a locknut and set screw projecting through the crankcase. The valves have cast iron heads 1⅜ in. o.d. welded to carbon steel stems. Connecting rods are drop-forged from .40 carbon steel. Lynite pistons with two hammered piston rings are employed. Both halves of the crankcase are of aluminum.

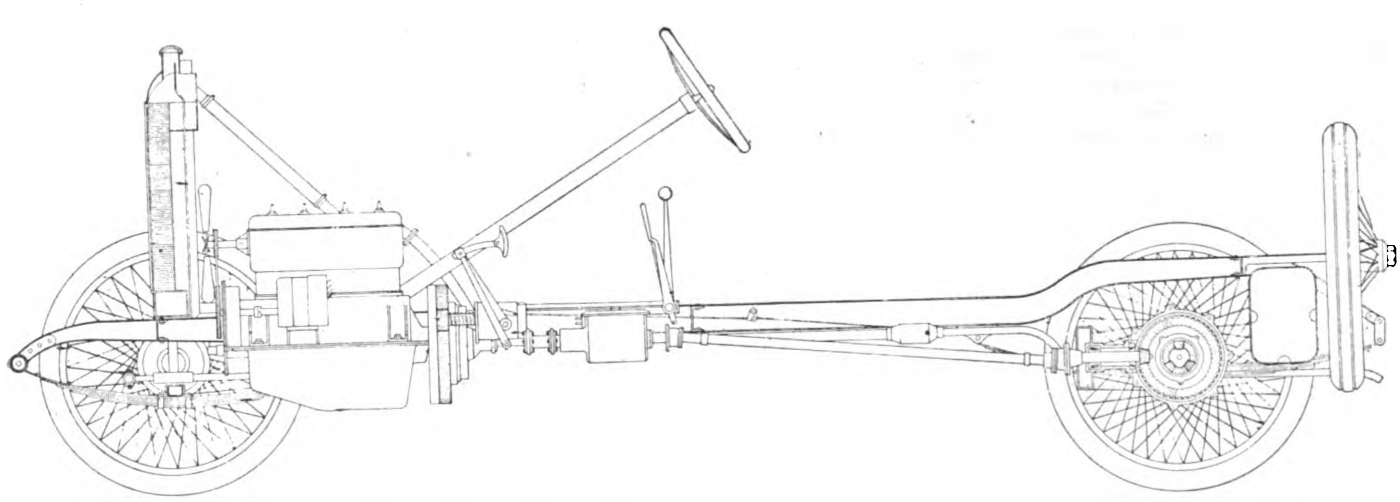
The engine is designed for high speed operation and is carefully balanced. It is said to be capable of speeds as high as 4000 r.p.m. It develops 20 hp. at 3000 r.p.m., at which speed it will, according to the manufacturers, drive the car at 60 m.p.h. with 4 to 1 gear ratio and 27 in. wheels.

Lubrication is by splash, the pump being bolted to the front plate of the distribution case, where it is readily accessible. Thermosyphon cooling is employed and the fan is belt driven. An attractive and distinctive honeycomb radiator with aluminum shell is fitted. Ignition is by Eisemann magneto. Bosch starting and lighting units are employed. These are carried on the subframe in which the engine and transmission are mounted and are located just forward of the gearbox. The generator is driven by a spring belt, and the starting motor is fitted with Bendix drive.

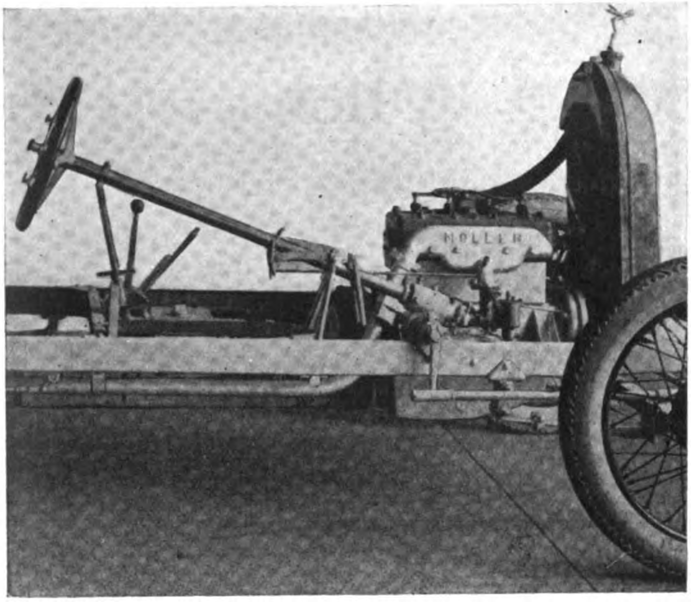
The clutch is of the multiple disk type. It has two driven plates and is enclosed by an aluminum case bolted to the flywheel. The gearbox is located amidship, following European practice, and is connected to the clutch by a shaft with two fabric disk joints. Gearbox and cover are of aluminum. The controls with *H* gate are located centrally above and just to the rear of the box. Three speeds are provided, the total reduction on low being 12 to 1 and on intermediate 8.68 to 1. The drive shaft is equipped with the smallest size of Spicer universal joints at each end. Hotchkiss drive is employed.

The final drive is by straight bevel gear to the semi-floating type of rear axle. The housing of the latter is of malleable iron. An interesting feature is the propeller shaft brake located on the axle just aft of the rear universal. This mounting gives the advantages of the transmission brake without transmitting the breaking stresses through the universals and propeller shaft. This brake is of the internal expanding type and is foot operated. The hand brake is also of the expanding type and is located on the rear wheels according to conventional practice.

The front axle is built up of square section seamless steel tube. The spindle yokes are welded into the ends of the tube, care being taken to secure an air tight joint so that water is excluded and corrosion prevented.



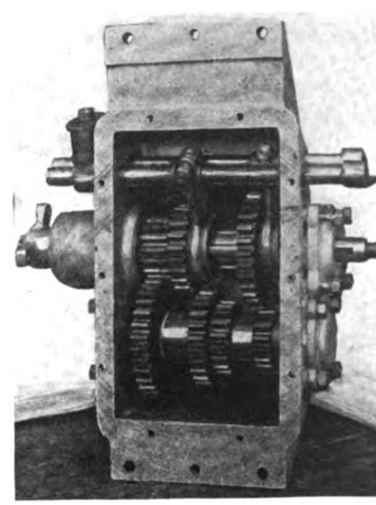
Side and part sectional view of the Moller light car chassis. Note location of foot brake on axle just aft of rear universal



Forward end of Moller chassis, showing adjustable steering gear and combined inlet and exhaust manifold.

Great care has been exercised in designing the spring suspension since the designers are convinced that the failure of many light cars has been brought about by failure to realize the importance, not only of easy riding, but of protecting the chassis parts from road shock and excessive stresses resulting from failure to provide proper springing. The entire chassis can be lifted by two men and the spring action is so soft that considerable deflections of the springs result from a rocking motion easily imparted to the chassis frame by one hand. The car is also easy running. It can be readily moved by grasping the propeller shaft in the hand and imparting to it a turning effort. All the springs are semi-elliptic. Those in front are 31 in. long and the rear pair 40 in. long. The leaves are tapered, being thinner at their outer ends, and made of silico-vanadium steel. Lubrication of chassis parts is provided by 21 Alemite connections where necessary.

The frame is of 1/8 in. pressed steel and has a 4 in. kick-up at the rear end. Three hot riveted cross members, one under the radiator, one just aft of the gearbox and the third just aft of the rear axle, are provided. The two forward cross members carry the subframe used to support engine and gearbox. Five Stewart wire wheels, with four 27 x 3½ in. clincher tires, are furnished as standard equipment. The road clearance is 8 in.



Amidship transmission used in Moller chassis.

The 5 gal. gasoline tank and the spare wheel are carried at the rear of the chassis. Fuel feed is by the Giorgio Georgy vacuum system to a 1 in. Zenith carbureter. Inlet and exhaust manifolds are cast in one piece, to provide heat to vaporize the charge. The car is claimed to make 35 miles per gallon of gasoline.

One of the novel features of the car is the adjustable steering gear. This is of the worm and wheel type and is mounted on top of the chassis frame, with the steering arm outside. It can be furnished for either right or left hand drive, as desired. The steering column can be raised and lowered from the driver's seat to suit the driver's convenience. It is locked in the desired position by an adjustable link, the forward end of which is connected to the dash.

It will be noted that nearly all the units in the car are designed especially for use in the Moller chassis. The small size and light weight of the car made it impossible to use many standard parts, hence the car is not an assembled product in the ordinary sense of the term, though many of the units are, for the present at least, being built outside the Moller factory—some of them by makers of standard parts. The aim of the Moller brothers, who are Danish engineers, has been to produce by American methods a high grade light car incorporating many European features of design and equipment, and primarily for sale in Europe.

Cars sold in the domestic market are expected to retail for about $2,000.

Motor Vehicles in Denmark

A CENSUS of motor vehicles has been taken in Denmark each year since 1909 except during the years 1918 and 1919. The latest census was held on Sept. 1, 1920, and showed that on that date there were in the country 11,594 private passenger cars, 2276 motor cabs and omnibuses, 3787 motor trucks and 12,182 motorcycles. The following table gives a general survey of the growth of motor transportation in Denmark:

Date of Census	Passenger Cars	Trucks	Motorcycles
Sept. 1, 1920	13,870	3,787	12,182
May 29, 1917	6,360	930	8,633
Sept. 1, 1916	4,995	723	7,766
Sept. 1, 1915	3,773	558	6,347
Sept. 1, 1914	3,079	351	5,248
Sept. 1, 1912	1,025	162	4,507
Sept. 1, 1910	920	77	3,478
Sept. 1, 1909	699		3,167

In connection with the above table it should be mentioned that in the figures for 1920 are included the cars, trucks and motorcycles in South Jutland, or that portion of Northern Schleswig which fell to Denmark as a result of the plebiscite last year. The census showed that district to possess 463 passenger cars, 41 motor trucks and 160 motorcycles. The rapid increase in the number of cars and trucks in Denmark during the past three years is noteworthy. The increase was especially great in the country districts.

ALL tests on recent aluminum solders have been completed by the Bureau of Standards, and Circular 78, "Solders for Aluminum," will now be revised to include these tests. In spite of claims made by those interested, no solder for aluminum has yet been found which will withstand the corrosion test, although the fused zinc chloride solders withstand corrosion for the greatest length of time.

Renault Now Producing Wheel Type Tractor

Has abandoned track-laying type and other tank features in new wheel type model which is much lighter than earlier machines. Built-up frame and axle with bevel and planetary reduction are employed.

By W. F. Bradley

FIRST of all French automobile manufacturers, Renault got into the agricultural tractor business a few weeks after the armistice with a track-laying type of machine based on his war tank design. Naturally the machine was lightened for the special work it had to perform, but in order to gain time some of the purely war tank features were retained. A later edition of the same tractor made its appearance a year ago with modifications suggested by a year's practical experience on the land.

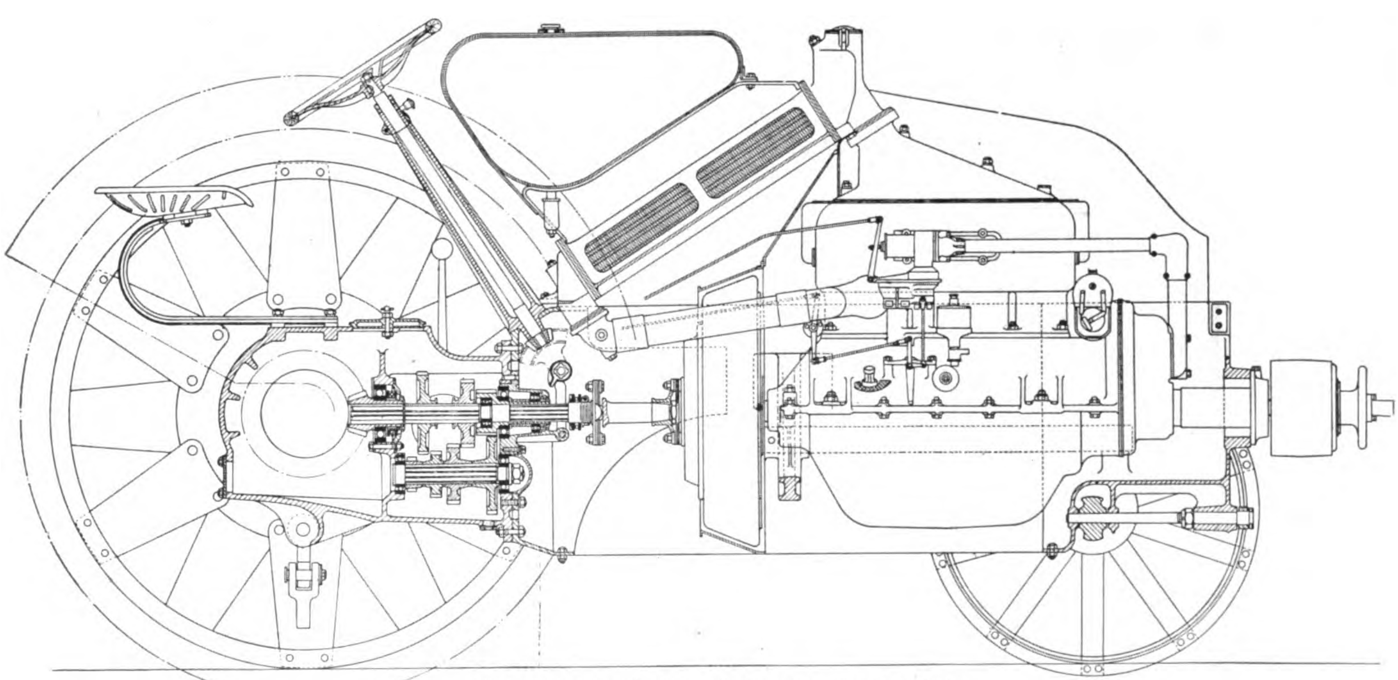
A third model of the tractor has now come forth, and although this is the direct successor of the war tank machines, all the military features have disappeared. Renault has abandoned creeper bands in favor of wheels, and although the two types are being produced, their capacities are so nearly alike that it is reasonable to suppose the endless track machine will ultimately disappear.

The engine is a block-cast, 95 x 160-mm. (3.74 x 6.3-in.), four-cylinder type, with fixed L-head, high-tension ignition, thermo-syphon water circulation, and a pump-circulated oiling system. This type of engine has long been standardized by Renault, for in addition to being used on his tanks, with a special lubricating system, it is employed on his 3-ton trucks. The radiator is placed back of the engine and inclined at about 45 degrees; a strong draft of air is assured through the tubes by the flywheel fan, and there is a lesser tendency for dust to enter under the hood than with the radiator mounted in front. An air washer is not used.

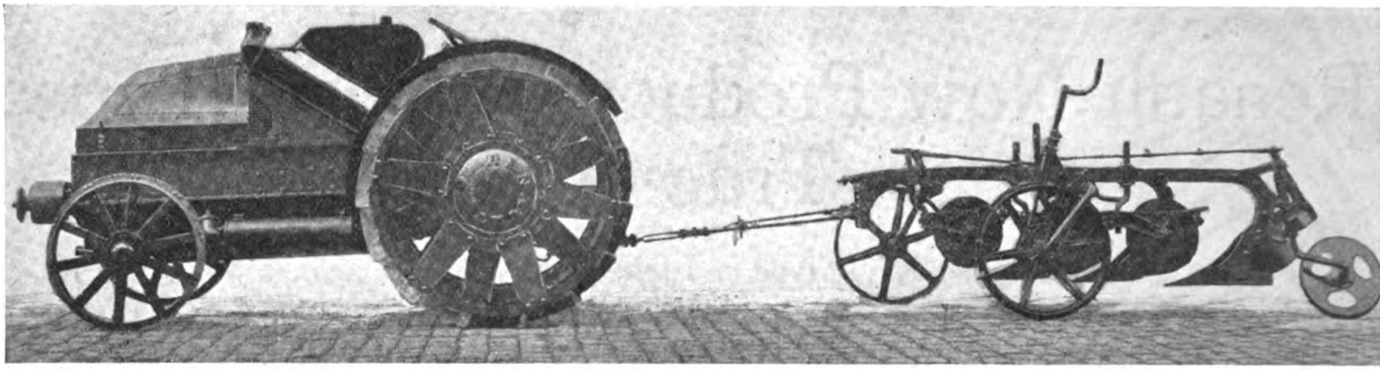
The new Renault tractor occupies a midway position between the frameless type of machine as represented by the Fordson and the automobile type with full frame. There are two channel section main frame members united at the front by a cast-steel cradle in which the front axle is pivoted, and at the rear by another cast-steel member which forms a face plate to which the united gearbox and differential housing is bolted. A channel section subframe carries the engine, and this latter is connected to the gearbox by a short shaft with two flexible steel disks. This design permits the use of the stock truck engine and at the same time reduces total weight of the machine compared with a frameless tractor. The total weight of the Renault wheel tractor is given as 2 tons, whereas the track-laying type machine, with the same engine, weighs more than 3½ tons.

The rear axle housing is built up with a cast-steel center and steel tubes, and forms a unit with the gearbox, the housing of which is also a steel casting. This unit is bolted to the face plate of the rear cross member of the main frame, in which is mounted the engine and radiator.

An inverted leather-lined cone clutch is used, and



Sectional view of the new Renault wheel tractor.



The Renault wheel tractor with plows attached. Note muffler carried below tractor frame

the gearbox gives three speeds and reverse, the ratios corresponding approximately to 1¾, 2½ and 7 miles an hour. Bevel gears give the first reduction from the drive shaft to the axle shafts, but there is a final reduction by planetary gears and internal spur pinion within the rear axle hubs. This type of final reduction has been in use for a considerable time on Renault 7-ton trucks and has given very satisfactory results.

The rear wheels are built up of sheet-steel rims with flanged edges and sheet-steel spokes riveted to the hub carrying the final reduction gears. Diameter of the wheels is 45½ in. and width 11 4/5 in. The front wheels are of the same design, and have a diameter of 27½ in. They are mounted on a straight axle, which is pivoted to the forward cast-steel cross member of the main frame. There are no springs, and, as the rear is rigid, the entire chassis pivots around the point of attachment to the front axle. A clutch-controlled pulley for belt drive is mounted on a forward extension of the crankshaft.

A Flexible Choke Valve

THE carbureters of practically all American cars are now fitted with a choke valve in the air inlet by means of which the vacuum around the spray nozzle can be increased while starting the engine and while warming it up, with the result that a richer mixture is fed to the engine than would otherwise be the case. This richer mixture is required because the fuel contains some constituents of very high boiling point which are not vaporized when the engine is cold and therefore really do not count in the combustible mixture. The ordinary choke valve is a butterfly valve which is controlled by hand from the driver's seat. One disadvantage of this type of valve is that with it the vacuum in the carbureter increases exceedingly fast with an increase in engine speed, and that then excessive amounts of fuel are drawn in.

A type of choke valve intended to obviate excessive enriching of the charge at the higher engine speeds is being marketed by the Gasoline Economy Co. under the name of the Winters flexible choke valve. It is in the form of a flap valve which is held to its seat by a coiled spring. The spring comprises quite a number of complete convolutions of wire, so that its torsional force is not very much different whether the valve is open or closed. As the speed of the engine increases, the increased suction opens the valve farther, but this increase in the opening of the valve in turn tends to keep down the suction. According to a test made for the manufacturers, the suction in the carbureter with the Winters flexible choke varied from 0.15 in. of mercury at 300 r.p.m. to 0.65 in. of mercury at 1500 r.p.m. and was then only imperceptibly higher than when no choke at all was used. With the regular choke, 30 deg. open the vacuum rose to 6.4 in. of mercury at 1,350 r.p.m. A rack and pinion mechanism is provided for easy adjustment of the spring force.

THE competition between road and rail transport may lead to a wasteful use of both these agencies unless steps are taken to effect the necessary degree of coordination. Arthur Watson, general manager of the London and North-Western and Lancashire and Yorkshire railways, dealt with this aspect of the question in a recent address to the Manchester Statistical Society. Although the committee which inquired into the subject was in the main hostile to the granting to railways of extended powers to engage in road transport, Mr. Watson believes that the telegraph and telephone communication systems established by railway companies could be utilized with advantage to organize transport by road as well as rail. Any fear of a universal transport trust being brought into existence by the intrusion of railways into the arena of road transport could, it was intimated, be dismissed as groundless.

Examples of European Practice in Three and Four-Point Suspension

Tendency is toward three-point type though majority of cars still employ the four-point arrangement. One maker employs a self-aligning ball bearing as support for extended front end of crankcase.

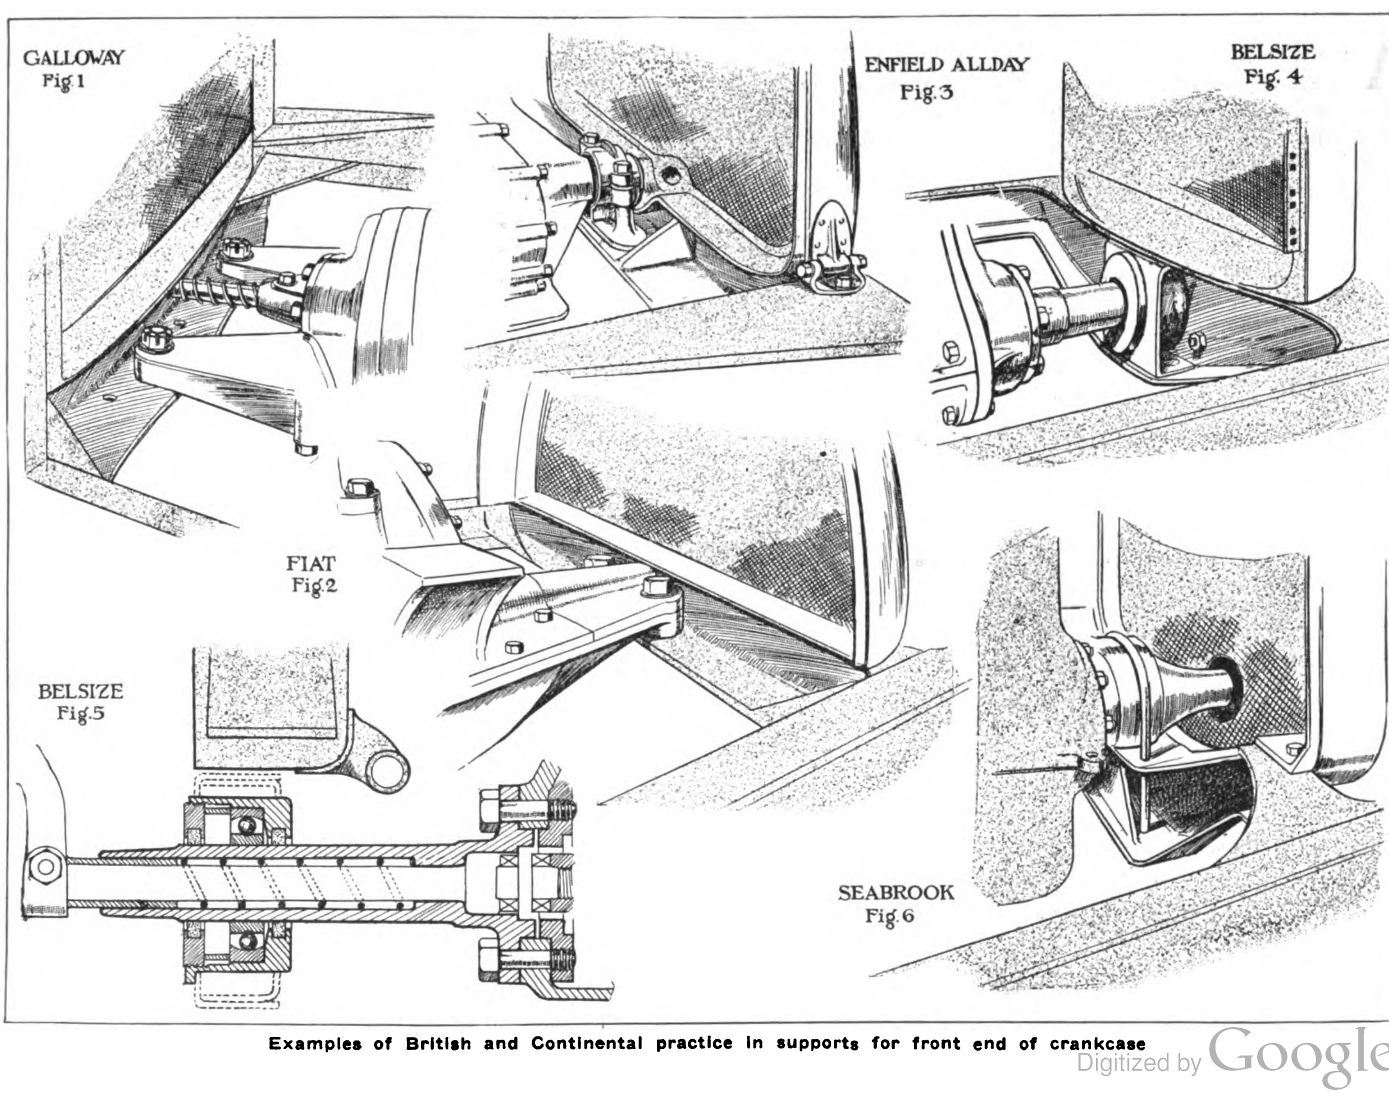
By M. W. Bourdon

THERE is a gradually increasing movement among European, and particularly British, designers to drop the four-arm crankcase in favor of a three-point support for engine or power unit, though admittedly the majority of European cars still have the former or some equivalent—for example, a four-point supported sub-frame or side extension webs of the crankcase.

But when the three-point arrangement is aimed at there is a great divergence in the manner in which the object in view is approached. Some designers apparently fear to go all the way, and, while discarding the two front arms extending from the side of the crankcase, still retain a two-point front end support. Examples of this compromise are seen in Figs. 1 and 2 herewith, the first being a sketch of the Galloway (one of the productions of the Beardmore interests), the second illustrating the Fiat front end.

Obviously the latter approaches nearer to the three-point ideal, and, compared with some single front end suspensions, is clearly a cheaper arrangement to produce. But, like the Galloway arrangement, it is a four-point suspension, nevertheless, and something has to yield when there is frame distortion; probably the frame webs accommodate themselves to the conditions of the moment.

The hemispherical trunnion bearing for the nose of the crankcase, somewhat on the lines of that shown in Fig. 3, is most usually favored by engine designers with



Examples of British and Continental practice in supports for front end of crankcase

three-point suspension in view. In the case illustrated the cross member is an angle casting with stiffening webs each side of the center, as shown; but as a rule a pressing of the usual channel section is favored, which necessitates a modification of the trunnion bracket—unless there is a pronounced dip in the cross member or a relatively high crankshaft center. This modification generally consists of securing the bracket to the vertical web of the pressing by horizontal bolts. But whether the bracket be supported as shown or otherwise, a split bronze bushing with a parallel bore and hemispherical exterior surface is almost invariably an accompaniment, with a grease cup in the bracket cap.

What is probably unique in front end engine mountings is the arrangement shown in Figs. 4 and 5, which is used on the Belsize, a medium-priced British car. To secure the effect of a spherical attachment to the frame the front extension of the crankcase is encircled by a self-aligning ball bearing mounted within a cage or cylindrical housing, itself supported by a piece of reversed channel steel riveted to the front cross member. Two felt gland washers are used, the front one located in a groove of a ring nut screwed into the bearing house from the front. A point about this mounting is that it allows for end movement between the parts, besides providing a spherical mounting, for the crankcase extension is not secured axially to the inner ball race or to any other detail. Apart, however, from direct considerations of cost, this Belsize mounting is open to criticism owing to the difficulty of insuring perfect alignment of the holes in the riveted channels for the bearing housing.

The last example, shown in Fig. 6, has greater possibilities as a production job, though the illustration represents the front end engine support on a British car (the Seabrook) with a very small output. The front end extension of the crankcase is, seemingly, larger than need be, though this is a fault on the right side in view of the fact that in this case it is of aluminum. The need for welding a triangulated web stiffener within the channel of the cross member will probably constitute no objection to the production expert, in view of the elimination of that *bête noir* of the machinist—*i.e.*, a spherical surface.

This last scheme is obviously capable of improvement. In the first place, the aluminum surface in contact with the cross member will clearly soon be indented and become a source of noise and hammering. But it should not be difficult to overcome this in a simple and cheap manner—if merely by the provision of a cradle of brass or steel, located by the U bolt, to form an immediate support of quite considerable area. Admittedly, this arrangement, lacking a spherical bearing, would not provide the ideal front end support for a three-point suspension, but it would go a very long way and take up the effects of frame distortion.

An Oil Pressure Reservoir

AN oil gun designed for use in a chassis lubricating system consists of a nickel plated metal bottle in which are located a piston and a heavy coil spring. The oil is contained in the upper part of the bottle and is put under pressure by the piston and coil spring. A length of flexible tubing is attached to the top of the bottle and the end of the tubing is equipped with a check valve which is released by the special fittings which replace the grease cups and oil cups on the car.

In fitting the gun, the cap at the top should not be removed until the full tension has been taken off the piston by contracting the spring to the fullest possible extent. This is done by inserting through a hole in the bottom of the bottle, the long, threaded rod which is supplied with the outfit. This rod contracts with a socket in the bottom of the piston. The rod is screwed into place and then the nut run up this rod as far as it will go. Then the wrench is used to bring the piston back to as near the bottom of the bottle as possible. This comprises the spring and releases all pressure from the top of the bottle. The cover is then removed and the bottle is filled, the cap replaced, the tension taken off the spring by turning back on the nut at the bottom, the threaded rod removed, the bottom cap replaced, and the oil gun is ready for service.

The device described is known as the Romon oil gun and is manufactured by Roberts & Monroe.

An Optical Pyrometer

A SIMPLE and cheap optical pyrometer known as the Pyromike has been developed in England by the Rudge-Whitworth Laboratories. It weighs only 5½ ounces and can be carried in the vest pocket. It is suitable for measuring all temperatures from a red heat upward. Its appearance resembles one-half of a pair of binoculars, or a little telescope 1¼ in. diameter by 2¼ in. long. Within the body of the instrument is a cell, composed of two circular glass disks joined by a piece of rubber tube, the latter being surrounded by a spiral spring. This cell is filled with colored liquid, and can be collapsed lengthwise by the rotation of the end of the instrument relatively to the eyepiece and body. The amount by which the cell is shortened is read off a graduated scale on the barrel, somewhat similar to that of a micrometer. To determine the temperature of any article, the latter is looked at through the instrument, and the cell slowly lengthened by rotating the end ring until the article ceases to be visible on account of the increased length of the light-absorbing liquid which has to be traversed by the light. The temperature can then be directly read from the scale engraved on the body. Each instrument has a total range varying from 250 deg. to 600 deg. C., depending on the kind of temperature which it is specially arranged to measure.

An Analysis of Elements Which Govern Automobile Fuel Economy

Part II.

The influence of air-fuel proportions, metering characteristics of carbureters, mechanical efficiency at part load, ignition timing and the size and speed of engines, is considered. A summary of theories and facts relating to fuel knock is also given, with pertinent comment thereon.

By H. C. Dickinson, S. W. Sparrow and R. L. Wales*

Influence of Air and Fuel Proportions Upon Engine Efficiency and Power

THE carbureter exists to proportion air and fuel so that the engine can deliver its maximum power or attain its maximum efficiency. Experiments to determine what these proportions should be have been made usually upon multi-cylinder engines. Faulty distribution influences the results thus obtained, since it necessitates an excess of fuel being supplied to some cylinders in order that the other cylinders can receive sufficient fuel for satisfactory operation. These results are, however, of immediate value, as they show what proportions the carbureter must furnish to cope with the faults of existing induction systems and yet give satisfactory engine operation.

The chemical combining proportion of air and a given fuel is a fixed quantity. In practice, a lower air-fuel ratio usually gives greater power and a higher air-fuel ratio greater economy. One reason for this is the lack of an intimate mixing of the air and the fuel. Supplying excess air tends to make certain that all the fuel is intimately associated with sufficient air to insure its combustion and thus to attain the maximum economy.

Investigators are in fairly close agreement as to the air-fuel proportions for maximum power, finding ratios of from 11 to 1 to 13 to 1 best in this regard for ordinary gasoline. A recent series of tests at the Bureau of Standards has shown that with an aviation engine having compression ratios of 5: 3, 6: 3, 7: 3 and 8: 3, the maximum power was obtained with air-fuel ratios of from 13 to 1 and 14 to 1, with air densities of from 0.025 to 0.075 lb. per cu. ft. This was, however, with aviation gasoline, a more volatile product than the commercial fuel.

Work done at the Bureau of Standards and elsewhere shows that the efficiency with any proportions with which the engine will operate is independent of the power developed. The same conclusion seems to have been reached by Ricardo. Failure of the engine to operate properly at very low loads with mixtures as lean as those giving maximum efficiency at greater loads seems to be due to dilution by the residual products of combustion. In present types of automobile engine the maximum power is obtained with air-fuel ratios of from 11 to 1 to 13 to 1 and the maximum efficiency at ratios in the neighborhood of 16 to 1, if the engine will operate regularly with such mixtures. Where dilution by the products of combustion necessitates richer mixtures, the maximum efficiency is attained with the leanest mixture at which the engine will operate regularly.

Metering Characteristics of Carbureters

As any wide departure of the mixture ratio from that corresponding to the maximum economy with a changing load on the engine may mean a serious waste of fuel, the load-mixture characteristics of several widely used carbureters are of interest. It might be assumed that since the pressure reduction causing fuel flow depends on the velocity, at a constant density, through the venturi in the normal type of carbureter, the gasoline discharge, and consequently the mixture ratio, would be determined solely by the weight of air used per second, or by the engine load. It is to be remembered, however, that a given weight of air may be used under very many different combinations of throttle position and manifold depression, corresponding with different relations of torque and speed of the engine. Experiment shows that with the usual location of the throttle, throat suction and, consequently, mixture ratios are affected not only by quantity of air passing but by the degree of opening of the throttle itself. Tests at the Bureau made with six widely used carbureters for various rates of flow, each at several relations of throttle position and manifold depression, show that the mixture ratio varies in one case from about 10 to 1 to nearly 17 to 1, and between still wider limits when comparing the different makes of instrument. The actual mixture proportions depend largely upon the particular adjustment used, but the change in proportions with change in load involve decreased economy under some conditions.

The Mechanical Efficiency of Engines, with Particular Reference to Part-Load Conditions

The mechanical efficiency of the engine is the ratio of the power delivered at the clutch to that developed in the cylinders. The difference between these two powers is used to overcome the internal friction of the engine, drive the auxiliaries and draw in and exhaust the charge. All of this power loss is included in the term "friction horsepower," although some of the elements are not due, strictly speaking, to friction. Thanks to the widespread use of the electric dynamometer, the determination of this friction horsepower is comparatively easy. It con-

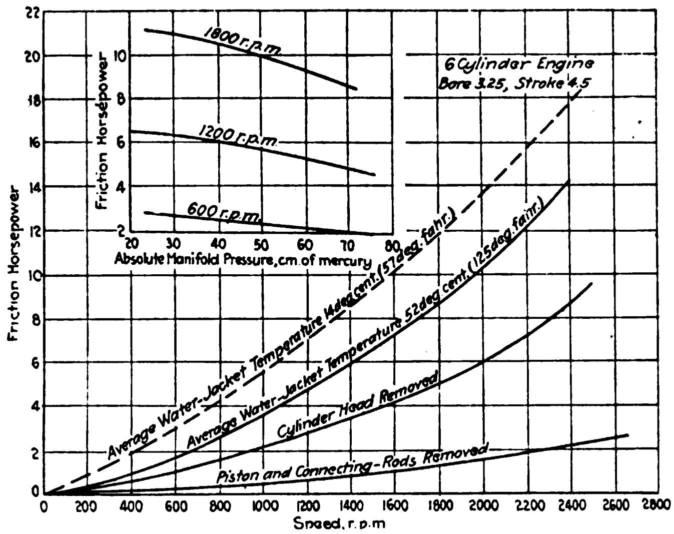

Fig 2—Relation between Friction Horsepower, Speed and Manifold Pressure Under Various Conditions.

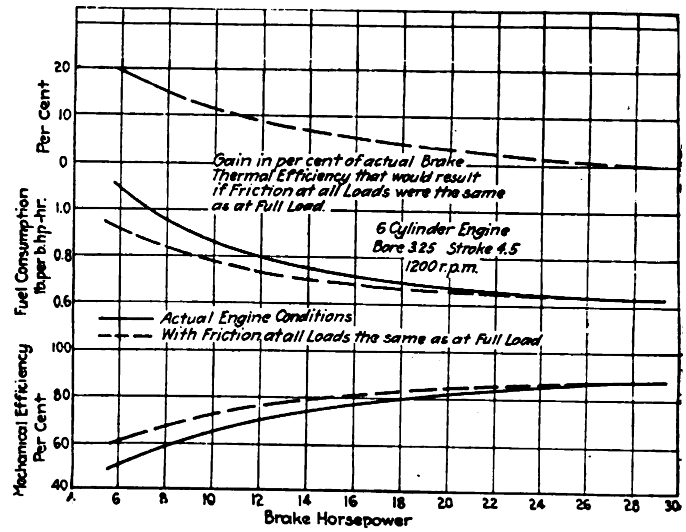

Fig. 3—Results of Tests on a Six-Cylinder Engine Showing the Relation Between Mechanical Efficiency, Fuel Consumption and Brake Horsepower.

sists in measuring the power required to drive the engine without fuel or ignition, while keeping all conditions as nearly as possible the same as when the engine is operating under its own power.

Fig. 2 makes clear the need for maintaining the jacket water temperature at its normal value during such determinations. At 1000 r.p.m. the friction with a jacket water temperature of 14 deg. C. (57 deg. Fahr.) is more than 50 per cent greater than when the temperature is 52 deg. C. (126 deg. Fahr.). This difference is a consequence of the higher viscosity of the oil at the lower temperature. One should not infer from these curves that the proper viscosity for an oil is that which gives the minimum friction. The viscosity must be high enough to prevent metal-to-metal contact, even when the oil is diluted with fuel. Nevertheless, the curves do illustrate the excessive friction loss that will ensue from use of oil of a viscosity unnecessarily high.

Comparison of Frictional Losses

A rough comparison of the magnitude of the several elements that comprise the friction loss is given by the lower three full-line curves. The results show piston friction to be responsible for a large proportion of the total loss. At 2400 r.p.m., with the cylinder head removed, the power required to drive the pistons and the connecting rods is three times as great as that to operate all the rest of the engine.

It is frequently assumed that the difference between the friction horsepower measured under normal conditions and that obtained with the valves or cylinder head removed represents the pumping loss. Values of the pumping loss obtained in this manner are considerably higher than those given by actual indicator card measurements. It appears, therefore, that the removal of the cylinder head not only eliminates the pumping loss but also reduces the piston friction through the change in pressures that results. This statement is made reluctantly because it has been found that the friction of the engine under power is not sensibly different from that when the engine is driven by the dynamometer, in spite of the lower pressures in the latter instance. At present the best that can be said is that measuring the pumping loss by this method of difference is open to question.

It is well known that the mechanical efficiency of the automobile engine decreases with a decrease in the load. One cause is the increase in the friction horsepower that results from closing the throttle. Fig. 2 shows this effect at three speeds, the absolute manifold pressures indicating the amount of throttle opening. That this is not the major cause of the low efficiency will be evident from Fig. 3. Here the mechanical efficiency and fuel consumption are plotted against the brake horsepower. The fuel-consumption calculations are based upon 0.55 lb. of fuel per i.hp.-hr., a value that is assumed to be constant over this load range. The dash line curves show results that might be obtained if the friction horsepower did not increase with the closing of the throttle. At 20 per cent load the upper curve shows a 20 per cent increase in the efficiency to be possible; that is to say, a car now going 15 miles on a gallon of fuel could then go 18. Even under these conditions, at 20 per cent load the specific fuel consumption would be 40 per cent greater than at full load. The low efficiency of the automobile engine is thus seen to be due primarily to the fact that it normally operates at a small percentage of its maximum power. This reserve power, however, if not actually a necessity, is at least a luxury that will not be willingly relinquished.

Emphasis may well be placed on the importance of keeping the friction as low as possible because its influence is multiplied at reduced throttle. For example, under the conditions of Fig. 3 an increase of 1 friction hp. would increase the fuel consumption at full load only 3 per cent, but at 20 per cent load, 9 per cent. Small gains in mechanical efficiency thus justify the expenditure of considerable effort toward their attainment.

Ignition Timing

The point in the cycle at which the ignition spark should occur in order that the engine efficiency may be a maximum is affected both by the speed of the engine and by its load. Many systems are constructed so that the timing of ignition changes with any change in the speed. There have been, in experimental use at least, devices which enabled the ignition timing to be controlled by the manifold pressure in an endeavor to meet the requirements of changing load.

There seems to be a dearth of experimental data on the amount by which the timing should be changed with changes in speed and load. Fig. 4 is typical of the data that are required. It shows the brake mean effective pressure obtained with various degrees of spark-advance for two speeds and three loads. The length of the blocks adjacent to the curves indicates the range of spark-

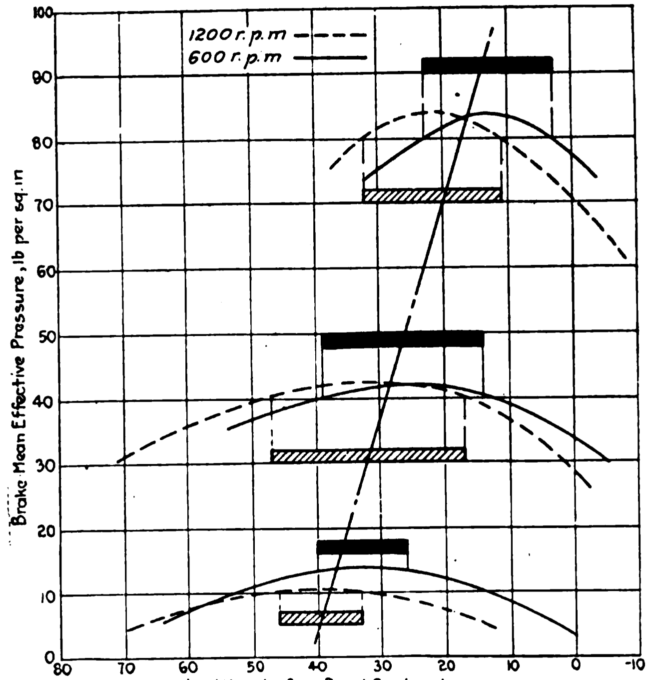

Fig. 4—Influence of Ignition Timing Upon Brake Mean Effective Pressure

timing within which the brake mean effective pressure will not be more than 5 per cent less than its maximum value. Inasmuch as the fuel consumption does not change appreciably so long as the speed and the throttle opening are kept constant, a change in the brake mean effective pressure means a corresponding change in the thermal efficiency. A compensation for load changes that would give the spark-advance brake-mean-effective-pressure relation shown by the dash line would be fairly satisfactory for the two speeds tested. Data of this sort should be obtained over the range of speeds and loads at which the engine will operate in service.

It is a common belief among automobile drivers that the maximum efficiency is obtained with the maximum advance at which the engine will operate without knocking. Under the conditions shown by the lower curves no knock was obtained even with the maximum advance, so that an adjustment in accord with the aforementioned belief would result in a decrease in efficiency of over 50 per cent. With manual control of spark-timing the possible advance should be limited to prevent this excessive loss of efficiency.

Fuel Knock

The phenomenon variously known as fuel knock, detonation and pinking has assumed so much importance because of the practical limitations it imposes on compression ratio and consequently on fuel economy that there has come to be much discussion and more speculation as to the exact nature of what takes place in an engine cylinder when this phenomenon occurs. However, neither the discussion nor the mass of information gained, directly and indirectly, from experiments has led to a definite understanding or even to a satisfactory theory of the nature of the phenomenon. The term detonation implies that something occurs in the cylinder which corresponds to the detonation of a high explosive. Such conditions are easily produced in explosive gas mixtures, but there is scant proof that the same thing occurs in an engine cylinder. In fact, some of the experimenters most familiar with these phenomena doubt the possibility of such occurrence.

To clear up some of the indefiniteness, an attempt has been made to enumerate the various facts and observations concerning fuel knock and to discuss the bearing of these facts on the several theories that have been advanced to explain the nature of the phenomenon. Fuel knock, as ordinarily understood, is characterized by the following phenomena:

(1) A very sharp metallic noise
(2) Bright yellow flame within the cylinder
(3) Decrease in power
(4) Increase in heat rejected to the jacket water
(5) High instantaneous cylinder pressure
(6) Destructive mechanical effects
(7) Occurrence of smoke in the exhaust
(8) Preignition, in most cases

Observations show that the occurrence and intensity of the knock are intimately related to the following factors:

(1) Chemical composition of the fuel
(2) Ignition timing
(3) Compression pressures
(4) Mixture ratio
(5) Position and number of spark-plugs
(6) Shape of cylinder and piston-head
(7) Temperature of the charge
(8) Cylinder temperatures

Aside from more or less random speculations, there are at least three rather definite theories or hypotheses presented as explanations of the character of this knock phenomenon. These are (*a*) what may be termed the mechanical-knock theory, which explains the sound by means of some mechanical knock or impact between parts of the engine mechanism—as, for instance, between cylinder wall and piston, or between shaft and bearings. This theory does not attempt to explain the cause of pressures which must exist to produce these mechanical impacts. On this theory it would be assumed that there is no necessary difference between the so-called fuel knock and any other purely mechanical knock, except that the former is primarily due to cylinder pressures, while the latter may be due to inertia effects, etc.

Ricardo's Fuel Knock Theory

Another theory (*b*) is that proposed by Ricardo, which explains the sound and other phenomena as due to a sudden very rapid increase in cylinder pressures. It is assumed that a portion of the charge, compressed to the ignition point by the expansion of the portion first ignited, burns simultaneously, causing a very sudden rise in pressure. This theory does not contradict the former, but assumes that the sound may be produced either by the sudden distortion of the cylinder walls by gas pressure or by mechanical impacts in the mechanism, due to the sudden pressure increase. It seems to require the assumption that a fuel will show a tendency to knock somewhat proportional to its spontaneous ignition temperature, but it makes no attempt to explain the nature of the explosion or detonation which occurs in the compressed charge.

A third theory (*c*), which may not necessarily contradict either of the foregoing, is the so-called detonation-wave theory. According to this the process of explosion is explained somewhat as follows: When ignited the wave of combustion spreads out from the ignition point at a relatively slow but increasing rate. Under certain conditions before the flame has filled the combustion space, its rate of motion increases to what is known as detonation velocity, a velocity so high as to constitute practically the simultaneous burning assumed by Ricardo. An interesting theory regarding the nature of the chemical reactions which account for the increase in flame

velocity has been proposed by Midgley. Such detonation waves in gas mixtures were first discovered in 1881, independently by Berthelot and by Mallard and Le Chatelier. These velocities and characteristics are reasonably well understood. The velocities are from 1 to 2 miles per sec., sufficient to account for the sound and pressure effects which are observed in engine cylinders. But in direct experiments it seems never to have been possible to attain these velocities within the short space in an engine cylinder.

Of the three theories, the first does not attempt an explanation of the phenomenon. Whatever causes the characteristic sound is certainly actuated by the sudden increases in cylinder pressure which have been measured repeatedly. The direct causes of these increases in pressure are of more interest than the source of sound, and the only attempt at explanation of sudden pressure increases is found in the theories (*b*) and (*c*); hence these appear of greater interest. In considering the bearing of known and observed facts on these theories, it is important to note that the one important difference between the two theories is that (*b*) assumes that the cylinder pressures are true pressures produced by a sudden increase of pressure throughout the cylinder, while (*c*) includes the assumption that the high pressure may be localized impacts of the detonation wave. This means that the maximum pressure may not be by any means the same at different points within the combustion space.

Phenomena Which Accompany Fuel Knock

The short metallic sound produced by fuel knock, particularly in light-weight cylinders, suggests the impact of a very light hammer on a heavy anvil. Observations of the velocities imparted to a light steel rod resting on the top of a Liberty engine cylinder during detonation show a number of interesting facts. For instance, it is found that under detonation conditions this cylinder head is distorted with a velocity which might correspond to that of a tuning-fork, corresponding to that of a sound having a pitch above the range of the piano keyboard, or of the order of 4000 vibrations per sec. The action of the cylinder pressure is, therefore, entirely sufficient to account for the characteristic sound produced.

The characteristic bright yellow flame within the cylinder, which is observed to accompany the fuel knock, has been shown by stroboscopic observations to be of very short duration, occupying not over 10 deg. rotation of the crankshaft or about 0.001 of a sec. in time. Evidently the flame phenomenon is worthy of more careful study as to its exact time of occurrence, its duration and the characteristics of the intermediate products of combustion. Such information might go far to explain the knock phenomena.

A decrease in the power output accompanies knock, but there seems to be no very close relationship between power and knock. Apparently fuel knock of itself does not reduce the power, but rather the conditions at which the knock occurs are not those for maximum power. Whether these conditions would produce the maximum power with a fuel that did not knock cannot be answered with certainty.

It has been observed that whenever fuel knock develops, due to a change in the timing or pressure, or a change in the fuel, there is an abrupt increase in the heat rejected to the jacket water. There are several possible explanations of this: (*a*) the increase in temperature and pressure may directly increase jacket losses by increasing radiation and convection to the cylinder walls; (*b*) the increase in pressure may increase leakage past the piston; (*c*) high-velocity detonation-waves, if they exist, may transmit energy to the walls by impact, and (*d*) the burning of oil directly on the cylinder walls, due to high temperature of the charge, may add to the heat loss.

Whatever the immediate cause of this increase of heat loss, the fact is significant. According to either of the two proposed theories, assuming localization and burning of a portion of the charge under increased pressure, it might be expected that the excess heating effect would be most pronounced at the particular location where this local combustion took place. Experiments to verify this by thermoelectric couples inserted in the cylinder in various positions with relation to the firing plug, show no significant difference in the temperature rise for different locations. These observations seem to show that the excess heating effect during knock is *not* localized as might be expected. The effects of increased radiation and of combustion of oil would be in accord with these observations.

Extremely high cylinder pressures have been found by different observers by various indicating devices. In one case, with a compression ratio of about 5 to 1, pressures of 1300 lb. per sq. in. were observed to occur consistently at each explosion; this pressure being the maximum measurable with the apparatus at hand. It is safe to assume that the maximum pressures were at least 1500 lb. and probably much higher. These pressures occurred with kerosene as fuel.

The amount and distribution of these pressures is of importance in relation to the two theories advanced. According to the Ricardo theory, the pressure may be uniformly distributed throughout the combustion chamber, although this is not a necessary assumption. If uniformly distributed, the pressure must not exceed that which could be produced by burning all the fuel at constant volume at intake pressure and then compressing adiabatically to the final volume. In fact, due to the nature of the process, the pressure can hardly exceed that which would be produced by compressing the charge adiabatically and burning it at constant volume under compression.

Possibility of Localized Pressure

On the other hand, the detonation theory presupposes that the maximum pressures are localized and places no limit on their magnitude below the calculated impact pressures of detonation waves in the compressed charge. This limit would be between 5000 and 7000 lb. per sq. in., but it is important to remember that these are not true sustained pressures, but resemble those produced by the blast from a high explosive; that is, they would last only a few millionths of a second. It is very doubtful if any indicator in use is capable of responding to such instantaneous pressures, other than to register a kick, so to speak.

As for experimental results, some indicator observations seem to show differences in the maximum pressures for different locations of the firing plug; other results worthy of equal confidence fail to show any such differences whatever. At the Bureau of Standards the maximum indicator pressure, the increase in combustion-chamber temperature and distortion of the cylinder head have all been carefully analyzed for different locations of the firing plug to detect any localization of pressures and none has been found. This appears to constitute strong evidence that no marked localization of pressure occurs which depends directly on spark plug location.

As noted above, the maximum pressures reached are occasionally as high as 1500 lb. per sq. in. at least. If they are normal uniform cylinder pressures, they cannot exceed the pressures that would be produced by com-

plete simultaneous combustion of the charge before compression, as stated. Moreover, from an examination of the pressure change it is evident that comparatively little of the charge is burned much before dead center; therefore, in practice, the knock pressures cannot exceed maximum computed pressures unless they are due to some effect other than normal combustion of the charge. Maximum pressure produced by the latter cause can be determined approximately. The maximum temperature reached on compression in the ratio 5 to 1 and combustion of a normal charge, taking account of dissociation, is given by Pye as from 2500 to 2700 deg. C. (4532 to 4862 deg. Fahr.). If dissociation is neglected, the temperatures are computed as about 3000 deg. C. (5432 deg. Fahr.). As the effect of dissociation is to lower the temperature, with a slight increase in volume relative to temperature, take the higher figure. This temperature corresponds to, roughly, 3250 deg. C. (5882 deg. Fahr.) absolute. If, therefore, the pressure were 1 atmosphere before compression and 5 atmospheres after compression, and the temperature 300 deg. C. (572 deg. Fahr.) absolute before compression, the pressure after compression and combustion has a maximum value of $5 \times 3250 \div 300$, or slightly over 50 atmospheres, which is about 750, or, say, 800 lb. According to Pye's results, the temperature would be only about 500 deg. C. (932 deg. Fahr.) higher and the pressure only about 1000 lb. per sq. in., if the combustion took place before compression. Pye gives 700 lb. per sq. in. as the maximum attainable cylinder pressure. This neglects the volume of water vapor which would increase the pressures somewhat.

Remembering that these are absolute maximum pressures if Pye's results are to be accepted, pressures of over 1000 lb. per sq. in. must be due to some cause other than normal gas combustion. In other words, such pressures cannot occur simultaneously at all parts of the cylinder.

Destructive Mechanical Effects of Knock

Destructive mechanical effects are somewhat difficult to interpret. Broken spark plug porcelains, cracked piston heads and burned-out bearings, as well as general evidence of excessive mechanical stresses, accompany continued detonation, particularly in aircraft engines. But none of these effects is subject to direct measurement. An index of the nature of the pressure rises which accompany knock is had, as referred to above, by observing the height to which a light weight is projected from its seat on the cylinder head. A measurement of this height and of the deflection of the cylinder head per unit pressure change leads to the following conclusions, which can be readily computed from the following data:

(1) The maximum height is 1½ in. The deflection of the cylinder head at this point is 0.0005 in. for each 100 lb. per sq. in. rise of pressure.

(2) The rate of pressure increase required to produce this effect is, roughly, 7,000,000 lb. per sq. in. per sec.

(3) The pressure was found to rise about 550 lb. per sq. in. above normal maximum when detonation took place, and to produce this rise at the above rate would require less than 0.0001 sec.

(4) For the Liberty engine cylinder, the combustion flame must traverse the explosive mixture at a rate of *at least* 4500 ft. per sec. to produce this observed rise of pressure. It is of interest to note that this figure is in fair agreement with the detonation velocities found by Dixon for explosions in tubes.

The observed occurrence of black smoke in the exhaust may have many explanations. One of the most obvious, that it indicates incomplete combustion, is apparently contradicted by the observed fact that the indicated power, therefore the amount of energy liberated in combustion is at least as great with as without fuel knock. I know of no definite conclusions which can be drawn from this occurrence.

The frequent occurrence of preignition following violent fuel knock is a natural sequence of the increased amount of heat rejected to the jackets, spark plugs, valves, etc. It hardly needs any other interpretation.

With reference to the several factors which affect fuel knock, the general consideration that the phenomenon is intimately connected with the process of combustion would indicate that any change in conditions would affect fuel knock.

The very marked effect of the chemical composition of the fuel, and particularly of the addition of certain anti-knock compounds as demonstrated by Mr. Midgley and others, shows the extreme sensitiveness of the phenomenon. In this connection, it should be noted that the comparison of different fuels by these observers has shown that some fuels which readily ignite spontaneously do not knock, and vice versa. This seems to be strong evidence contrary to the spontaneous-ignition theory of Ricardo.

Effect of Ignition Timing

The effect of ignition timing has been shown by observations at the Bureau of Standards to be of very much more significance than previously supposed. For instance, it is proved that knock can be made to appear on cutting out one of two spark plugs, or under other conditions to appear when the second plug is switched in; and these effects are apparently due solely to the changes in the effective timing of the combustion relative to piston position. The use of two plugs in effect advances the timing. It is shown, also, that knock can be prevented much more readily and with less loss of power by careful regulation of ignition timing than had been supposed. However, it is difficult to draw any conclusions from these facts as to the nature of the fuel knock.

The other factors enumerated, such as the compression pressure, mixture ratio, temperature of the charge, and temperature of the cylinder, seem to offer no direct evidence as to th probable validity of the two theories under consideration. They might, however, afford valuable data if the nature of knock were better understood.

The number of ignition points and their relation to the shape of the combustion space seem to be of significance. It appears to be a fact that the larger the number of ignition points, and the nearer these are to all portions of the charge, the less is the tendency to fuel knock. The much-discussed subject of turbulence appears to be probably of significance mainly as it affects the distribution of the burning mixture. Distribution of burning charge should be nearly equivalent to distribution of ignition points. Obviously the maximum rate of pressure increase which can be produced by normal burning occurs with the greatest amount of flame area, but the larger the number of spark plugs the greater the total area of flame, at least at the beginning of the combustion; yet this maximum area never produces sudden pressure rises of the order observed. Something beside normal rates of burning are, therefore, necessarily involved.

The conclusions to be drawn are as follows:

(1) The two theories of fuel knock, that of Ricardo and the detonation wave theory, do not appear to be essentially contradictory but make somewhat different assumptions as to the maximum pressure.

(2) The sound produced by fuel knock can be adequately accounted for by the distortion of parts of

the cylinder, without assuming any metallic impacts.

(3) The excess heating effect accompanying detonation does not appear to be localized in any particular portion of the cylinder, as might be expected from either theory.

(4) No differences in maximum pressure when measured in different positions relative to the point of ignition have been definitely demonstrated, although some observations indicate them.

(5) The maximum pressures measured seem to exceed those which could be produced by the normal explosion of the charge. This indicates that some phenomenon such as detonation must be assumed to account for the pressures observed.

(6) The rates of increase of pressure which have been observed are such as to require the existence of some such disturbance as detonation, as an adequate explanation.

(7) It has been shown that fuels which are particularly subject to auto-ignition by compression are not necessarily subject to fuel knock. This indicates that the spontaneous ignition theory of Ricardo, in its simplest form, is at least incomplete.

From the foregoing it may be concluded that whatever the phenomenon of fuel knock may involve, the observed facts are in reasonably close agreement with the theory that the high pressures and attendant phenomena are the result of an abnormal type of combustion which can be accounted for with a reasonable degree of completeness by the so-called detonation theory. The only serious discrepancy between this theory and the observed facts appears to be the failure to discover positions within the cylinder where maximum pressures and temperatures occur. If it can be assumed that the impact waves, which are taken as an explanation for the very high pressures, are capable of reflection within the combustion chamber, the hypothesis of localized maximum pressures is not essential to the theory.

Relative Merits of Large Slow-Speed and Small High-Speed Engines

For comparison one engine is assumed to have a piston displacement 50 per cent greater than that of the other. Rear-axle ratics are taken as 3 and 4.5 for the large and the small engine, respectively, in order that substantially the same torque can be delivered to the rear wheels in each case. Rather than inject a detailed analysis of the relation of friction losses to piston displacement, it is assumed that the increase in displacement is obtained by adding two cylinders to a four-cylinder engine and that the friction power is increased 50 per cent thereby.

A fuel consumption of 0.55 lb. per i.hp.-hr. has been used in the calculations for all conditions of engine speed and load. Tests made thus far at the Bureau of Standards indicate that the efficiency for a given load is independent of the speed over the range of speeds covered in this discussion. One further assumption, the relation of friction horsepower at part load to that at full load must precede the calculation of fuel consumption per brake horsepower-hour. An approximate relation, derived from tests on an automobile engine has been used for this purpose.

In calculating the fuel consumption in pounds per brake horsepower-hour, the first step is the determination of the brake horsepower developed at the speed selected. The brake horsepower developed at full load at that speed is also determined, and hence permits the percentage of full load at which the engine is operating to be deduced. Knowing this, the friction horsepower can be obtained by the relationship between the friction horsepower at full and part load, given in Fig. 5. Three steps remain: (*a*) the addition of the friction horse-

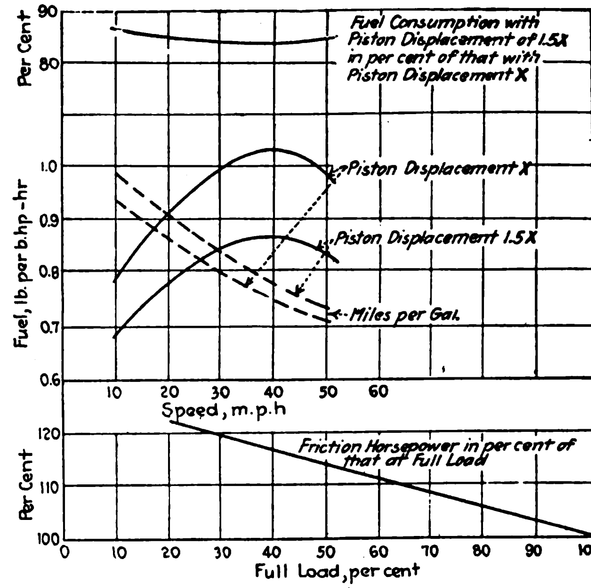

Fig. 5—The relation between fuel consumption and the friction horsepower at full and part loads

power to the brake horsepower to obtain the indicated horsepower; (*b*) the division of the brake horsepower by the indicated horsepower to obtain the mechanical efficiency; (*c*) the multiplication of the fuel-consumption expressed in pounds per indicated horsepower-hour (0.55) by the mechanical efficiency, to obtain values of fuel consumption in pounds per brake horsepower-hour. Results calculated by this method are given in Fig. 5.

Percentage values, given in Fig. 5, show the larger engine to have a 15 per cent lower fuel consumption than the smaller engine. This figure is unfair to the small engine, as the increased weight of the large engine means that the ability of the car is reduced. Published data show that usually in a series of engines built by any one company, the weight per brake horsepower is less the greater the horsepower. Let this effect be neglected to take care of any weight increase in the transmission and drive required by the larger engine and let the increase in the engine weight be 50 per cent. As the engine-weight is about 15 per cent of the car weight, the weight of the latter will be increased 7.5 per cent. It is concluded, therefore, that the car has lost 7.5 per cent in ability and gained 15 per cent in economy. Furthermore, it is evident that increasing the large engine until its ability equals that of the small engine will still leave it somewhat superior from the standpoint of economy.

The foregoing analysis does not prove the superiority of either type of engine for every case. Engine cost, durability, relative ability for slow speed operation and many other factors must influence such a decision. There is a widespread belief that the small high-speed engine is vastly more efficient than the larger slow speed type. The purpose of this discussion is to challenge that belief and to show the factors of major importance in the comparison of the two types.

A PHOTOGRAPH of a California motorcycle hill climb contest was published recently in the British journal *Motorcycle*. This picture showed a rider, his machine almost turned over backward, in an attempt to climb a gradient of 1 in 2. The caption was "American Conception of a Hill Climb," and this comment was appended: "Such stunts are purely spectacular, and while exciting for the onlookers and riders, in no way help to advance design as do events in this country (England)." Here is a criticism worth considering both as regards motorcycles and automobiles.

Running Balance and Uniformity of Crankshaft Effort in 8-Cylinder 60 Degree Vee Engines

The vibrating forces in an eight cylinder Vee engine are dealt with by the analytical method in this article. One conclusion reached is that the maximum vibrating force of the 60 degree eight cylinder engine is only 61.2 per cent of that of a 90 degree eight cylinder Vee engine.

By P. M. Heldt

EIGHT-CYLINDER engines have been built in at least four different types so far, namely with the cylinders all in line and as 90, 60 and 45 degree Vee engines. The original eight-cylinder engines for aircraft and automobiles were 90 deg. Vee engines, and this type has enjoyed the greatest popularity up-to-date. Eight-cylinder all-in-line engines were first used—at least as far as automotive practice is concerned — by Charron, Girardot & Voigt in France in 1902 and revived by Ballot in 1919. The first Liberty aircraft engine was a 45 deg. eight-cylinder Vee engine, and recently the 60 degree Vee eight-cylinder engine has come to the fore by its adoption for use on the Lincoln and Wills-Sainte Claire cars.

There are two main objects aimed at when going to the complication of an engine with as many as eight cylinders, namely, balance of the reciprocating parts and uniformity of crank effort or torque. If the explosions come at equal intervals the crank effort will be the same no matter whether the cylinders are arranged vertically or in Vee form. But with 45 degree and 60 degree Vee eight-cylinder engines it is impossible to get evenly spaced explosions if the ordinary four-throw crank is to be used, which is necessary for the sake of compactness. It is reported that the 45 degree Vee Liberty engine showed a great deal of vibration. Theoretically there are no greater vibrating forces in a 45 degree than in a 90 degree Vee eight-cylinder engine, but the direction of these forces is entirely different. Whereas the direction of the vibrating forces is nearly vertical in the 45 degree engine, with only slight horizontal components, in the 90 degree engine these forces are absolutely horizontal, and it is conceivable that an airplane is much more sensitive to vibrating forces in a vertical plane than in a horizontal plane, owing to its much smaller vertical rigidity.

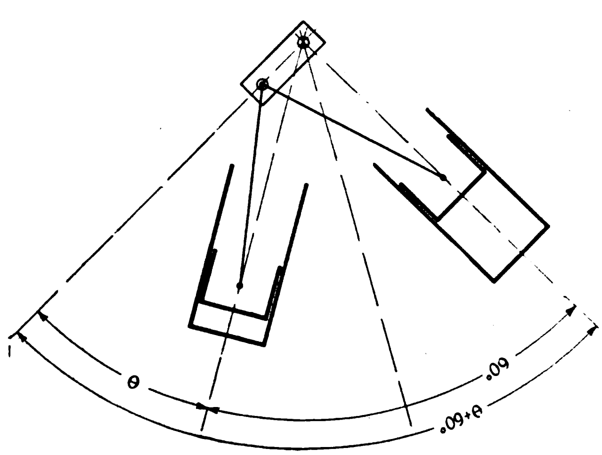

Fig. 1—Diagram of Vee engine

The writer first investigated the subject of vibrating forces in eight-cylinder Vee engines with different angles of Vee in an article printed in *The Horseless Age* of Feb. 1, 1916, and came to the conclusion that with a 60 degree angle of Vee the vibrating force is of constant value and uniformly rotating, the same as the vibrating force due to a rotating unbalanced weight. It rotates at twice the angular speed of the crankshaft and therefore cannot be balanced by weight rotating with the crankshaft. Its value is only about 61 per cent of the maximum value of the unbalanced force in a 90 degree eight-cylinder engine.

The method employed in the article referred to was partly analytical and partly graphical. It is, however, quite possible to deal with the problem by the analytical method alone. In doing this we can base our reasoning upon the fact that as far as balance of reciprocating parts is concerned the eight-cylinder Vee engine consists of two four-cylinder engines having a common crank axis and mounted at a certain angle relative to each other. We can obtain the instantaneous value of the vibrating force of the whole engine by combining corresponding vibrating forces of the two four-cylinder engines on the principle of the parallelogram of forces.

The vibrating force of a four-cylinder engine is

$$F_4 = \frac{2(0.0000142)\ W\,l\,N^2}{n}\cos 2\theta$$

where W is the weight of the reciprocating parts appertaining to one cylinder, in pounds; l, the length of stroke in inches; N, the number of revolutions per minute; n, the ratio of connecting rod length to length of stroke and θ the angle through which the crankshaft has turned from the top dead center position. We may write this in an abbreviated form as follows:

$$F_4 = \frac{2c}{n}\cos 2\theta$$

This is a harmonic force of twice the periodicity of the crankshaft revolutions, the so-called primary unbalanced force of the individual crank being entirely eliminated in the four-cylinder engine.

If we take the above expression as representing the un-

balanced force of the right hand set of cylinders in an eight-cylinder 60 degree Vee type engine rotating right-handedly, then the vibrating forces of the left hand set of cylinders can be expressed by

$$F_4 = \frac{2c}{n} \cos 2\,(\theta + 60 \text{ deg.})$$
$$= \frac{2c}{n} \cos\,(2\theta + 120 \text{ deg.})$$
$$= \frac{2c}{n} (\cos 2\theta \cos 120 \text{ deg.} - \sin 2\theta \sin 120 \text{ deg.})$$

We now have the instantaneous values of the vibrating forces for both sets of cylinders. These forces always act at an angle of 60 degrees to each other and the problem is to find their resultant.

In Fig. 2 the parallelogram of forces is shown, the diagonal c representing the resultant of the unbalanced forces due to the individual sets of four cylinders. We must now solve the problem of an oblique triangle of which two adjacent sides a and b and the included angle C are known, the value desired being that of c, the side opposite the known angle.

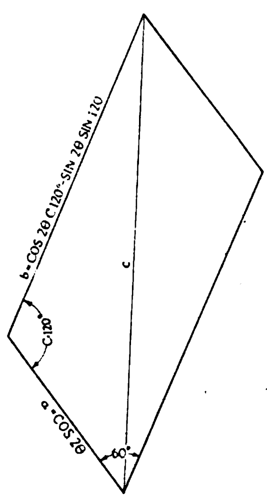

Fig. 2 — Parallelogram of vibrating forces in 60 deg. Vee engine

According to the rules of trigonometry, the value of c in terms of the other two sides and the included angle is:

$$c = \sqrt{a^2 + b^2 - 2\,a\,b \cos C}.$$

In our case

$$a = \frac{2c}{n} \cos 2\theta$$
$$b = \frac{2c}{n} (\cos 2\theta \cos 120 \text{ deg.} - \sin 2\theta \sin 120 \text{ deg.})$$
$$C = 180 \text{ deg.}$$

Since both a and b contain the factor $\frac{2c}{n}$, and there is a constant angle between them, c will also be proportional to $\frac{2c}{n}$, and we may therefore omit this factor in solving the triangle, thus making

$$a = \cos 2\theta$$
$$b = \cos 2\theta \cos 120 \text{ deg.} - \sin 2\theta \sin 120 \text{ deg.}$$

Substituting in the above equation for c—

$$c = \sqrt{\begin{aligned} &\cos^2 2\theta \\ &+ \cos^2 \theta \cos^2 120 \text{ deg.} \\ &+ \sin^2 2\theta \sin^2 120 \text{ deg.} \\ &- 2 \cos 2\theta \cos 120 \text{ deg.} \sin 2\theta \sin 120 \text{ deg.} \\ &- 2 \cos^2 2\theta \cos^2 120 \text{ deg.} \\ &+ 2 \cos 2\theta \sin 2\theta \cos 120 \text{ deg.} \sin 120 \text{ deg.} \end{aligned}}$$

The fourth and sixth term cancel out, leaving

$$c = \sqrt{\begin{aligned} &\cos^2 2\theta \\ &+ \cos^2 2\theta \cos^2 120 \text{ deg.} \\ &+ \sin^2 2\theta \sin^2 120 \text{ deg.} \\ &- 2 \cos^2 2\theta \cos^2 120 \text{ deg.} \end{aligned}}$$

Now, $\sin^2 120$ deg. = ¾ and $\cos^2 120$ deg. = ¼. Therefore,

$$c = \sqrt{\begin{aligned} &\cos^2 2\theta \\ &+ \tfrac{1}{4} \cos^2 2\theta \\ &+ \tfrac{3}{4} \sin^2 2\theta \\ &- \tfrac{1}{2} \cos^2 2\theta \end{aligned}}$$
$$= \sqrt{\tfrac{3}{4}\,(\cos^2 2\theta + \sin^2 2\theta)}$$
$$= \sqrt{\tfrac{3}{4}} = 0.866$$

Therefore, the vibrating force of an eight-cylinder 60 deg. Vee engine is

$$F_{8\text{-}60} = 0.866 \times \frac{2c}{n}$$
$$= \frac{0.866 \times 2 \times 0.0000142\, W\, l\, N^2}{n}$$
$$= \frac{0.0000246\, W\, l\, N^2}{n}$$

This shows that the vibrating force is independent of the crank angle and has a constant value. Graphically it can be represented by a circle.

The vibrating force of a 90 degree eight-cylinder engine is

$$F_{8\text{-}90} = \frac{0.0000402\, W\, l\, N^2}{n} \cos 2\theta$$

and its maximum value is

$$F_{8\text{-}90} = \frac{0.0000402\, W\, l\, N^2}{n}$$

The maximum vibrating force of a 60 deg. eight-cylinder engine therefore is only 61.2 per cent of the maximum vibrating force of an eight-cylinder 90 deg. Vee engine. On the other hand the vibrating force of the 90 deg. engine acts in a horizontal plane only, where vibration is damped by the lateral rigidity of the chassis springs, whereas the

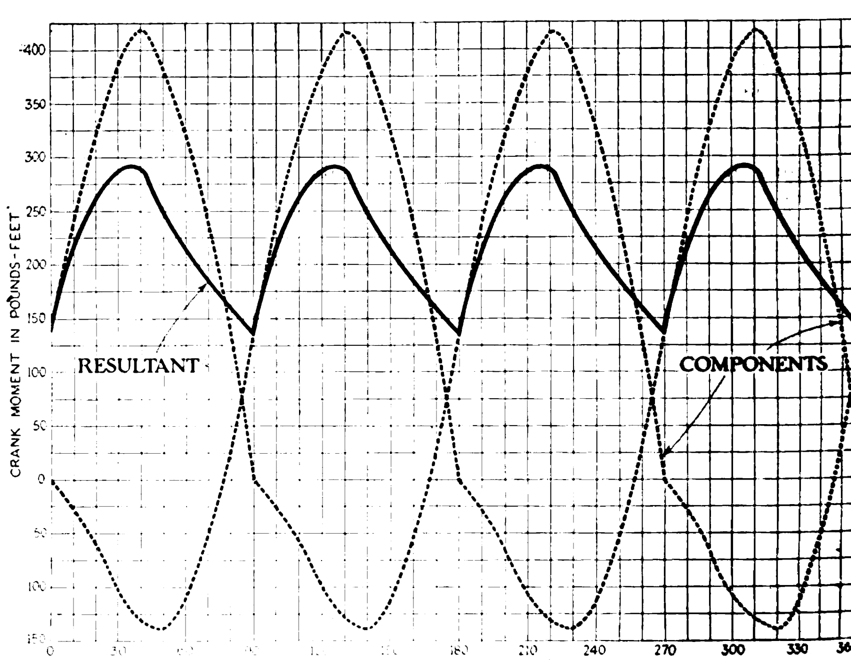

Fig. 3—Torque diagram of 90 deg. Vee engine

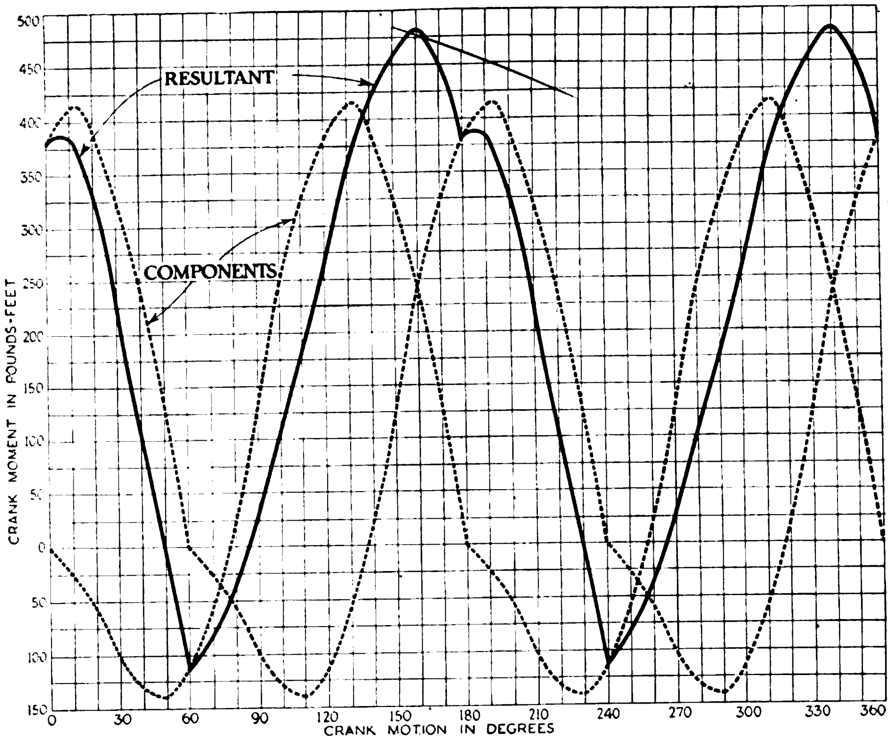

Fig. 4—Torque diagram of 60 deg. Vee engine

60 deg. engine tends to vibrate both vertically and horizontally.

In any eight-cylinder Vee engine using an ordinary four throw crankshaft there must be two explosions in every 180 degrees of crank motion, because that is the angular distance between successive explosions in cylinders of one block. In the 90 deg. Vee engine all explosions are evenly spaced and come at 90 deg. intervals. In the 60 deg. engine the explosions come at intervals of 60 deg. and 120 deg. respectively. In order to obtain a crank effort diagram we may take that of a four-cylinder engine and superpose upon it another one displaced 60 deg. with respect to the first for the 60 deg. engine, and 90 deg. for the 90 deg. engine; adding the two curves thus superposed in each case we get the crank effort diagrams of the 60 deg. and 90 deg. engines. These diagrams are shown in Figs. 3 and 4. It will be seen that the torque fluctuations are much greater in the case of the 60 deg. engine than in that of the 90 deg. engine. In the 60 deg. engine for the conditions assumed the torque varies between — 110 and plus 483 lbs.-ft. and in the 90 deg. engine for the same conditions between plus 140 and plus 290 lbs.-ft. The average torque is the same in both cases.

The maximum unbalanced force in an eight-cylinder 45 deg. Vee engine may be found in a way similar to that used above for the 60 deg. engine. In this case it is preferable to measure angles from the radial line midway between the axes of the two sets of cylinders. The unbalanced force of the right hand set of cylinders will then be

$$F_r = \frac{2c}{n}\cos 2\,(\theta + 22.5^\circ)$$

$$= \frac{2c}{n}\cos\,(2\theta + 45^\circ)$$

$$= \frac{2c}{n}\,(\cos 2\theta \cos 45^\circ - \sin 2\theta \sin 45^\circ)$$

$$= \frac{2c\,\sqrt{1/2}}{n}\,(\cos 2\theta - \sin 2\theta)$$

and that of the left hand set of cylinders

$$F_l = \frac{2c}{n} = \cos 2\,(\theta - 22.5^\circ)$$

$$= \frac{2c\,\sqrt{1/2}}{n}\,(\cos 2\theta + \sin 2\theta)$$

In combining these two forces by the parallelogram of forces we may neglect the factors outside the parentheses, as they are the same for both sides of the triangle, and will therefore also appear in the third. We then have an oblique triangle of which two sides and the included angle are known, and the problem is to find the value of the side opposite the known angle, which is the resultant of the two component forces.

$$a = \cos 2\theta - \sin 2\theta$$
$$b = \cos 2\theta + \sin 2\theta$$
$$c = 135^\circ$$
$$c = \sqrt{a^2 + b^2 - 2ab\cos C}$$
$$= \sqrt{2\cos^2 2\theta + 2\sin^2 2\theta - 2\,(\cos^2 2\theta - \sin^2 2\theta)\cos 135^\circ}$$
$$= \sqrt{2 + 2\sqrt{1/2}\cos^2 2\theta - 2\sqrt{1/2}\sin^2 2\theta}$$

In order to determine for what value of θ this expression is a maximum we should differentiate it, place the first differential coefficient equal to zero and solve. It is obvious, however, that the expression reaches its maximum value when $\cos 2\theta = 1$ and $\sin 2\theta = 0$, that is when $2\theta = 0$ deg. For this case we have

$$c = \sqrt{2 + 2\sqrt{1/2}} = 1.848$$

Multiplying this by the factors which we neglected when finding the resultant of the two forces we get

$$\frac{2c\,\sqrt{1/2}}{n} \times 1.848 = \frac{2.613\,c}{n}$$

Further, since

$$c = 0.0000142\,W\,l\,N^2,$$

we have, finally, for the maximum force of unbalance of an eight-cylinder 45 deg. Vee engine

$$F_{8-45} = \frac{0.0000371\,W\,l\,N^2}{n}$$

Therefore the maximum unbalanced forces in eight-cylinder Vee engines with angles of Vee of 45, 60 and 90 degrees, bear to each other the relation of

371 : 246 : 402

This, however, does not mean that the amplitudes of vibration of the car will bear the same proportion to each other when engines of the different types are fitted, because these maximum vibrating forces act in different directions and the resistance of the chassis to vibration is different in different directions.

AT the plant of the Baush Machine Tool Co. worms for automobile drives are hardened by quenching after being heated in a cyanide bath. The worms have previously been carbonized, and the object in heating in cyanide is not to form a thin surface layer of carbonized metal as might be surmised, but to prevent decarbonization of the surface layer while being heated and the formation of a layer of oxide while the worm is being transferred to the quenching bath. The cyanide is contained in a pressed steel pot and has a low-pressure oil fire under it. There are two furnaces side by side, with a common chimney to carry off the combustion products.

A New System of Gear Grinding and Gear Inspection

Great accuracy of tooth and more rolling with less sliding action are claimed. Grinding machine works on generating principle and means for compensating for wear of grinding wheel is provided.

By P. M. Heldt

THE Maag system of gearing, due to Max Maag of Zurich, Switzerland, has been before the engineers of this country for some years. These gears are characterized by teeth of true involute form. In order to avoid interference in pinions with a small number of teeth, such pinions are made with a relatively small dedendum and large addendum, and the mating gears with a large dedendum and small addendum. In fact, the proportional dimensions of addendum and dedendum depend upon the gear ratio. In a pair of gears giving a large ratio there is a large difference between the addenda of the pinion and gear, while in a pair of gears for a 1-to-1 ratio, the addenda are equal, as are also the dedenda. Thus a pinion made by this process will run properly only with a gear of a certain number of teeth made by the same process. There is no definite pressure angle in this system, the angle varying somewhat with the point of contact along the tooth flank. It is claimed for the Maag form of tooth that with it there is more rolling and less sliding action than with other forms of gear teeth. Another advantage claimed is great accuracy of tooth outline, due to the fact that the teeth are formed on the generating principle by means of a rack-shaped cutter, the sides of whose teeth are straight lines.

Mr. Maag has recently developed a gear grinding machine embodying some novel features. This permits of making the gears of low carbon or alloy steel, case hardening them, and then, after hardening, correcting any distortion that may have occurred in the grinding machine. One of the difficulties in gear grinding in the past has been that, owing to wear of the cutting surfaces of the grinding wheel, the tooth spaces will gradually become narrower. The Maag gear grinding machine works on the generating principle, the same as the gear cutting machine. The grinding is performed by means of two saucer-shaped wheels which are set apart and inclined toward each other in such a way that the planes of the saucer lips coincide with the flanks of one tooth of the rack cutter if superposed upon same. The gear wheel to be ground is mounted on a horizontal axis and is fed longitudinally beneath the revolving grinding wheels. As it passes beneath the grinding wheels the gear wheel is reciprocated transversely through a short distance and at the same time is rocked through a corresponding angle, the two movements being correlated so as to exactly reproduce the movement of the gear wheel if it were rolled without slipping, on its pitch circle. A true rack and pinion action is thus obtained, the same as in the cutting machine, but in this case, as the rack has only one tooth, the work has to be indexed relative to the grinding wheel once for every tooth space. The arrangement shown in Fig. 1 is used for gear wheels above a certain minimum pitch. The tooth spaces of gears of small pitch are of insufficient width to permit of both grinding wheels working within them at the same time, and in that case adjacent spaces are ground simultaneously.

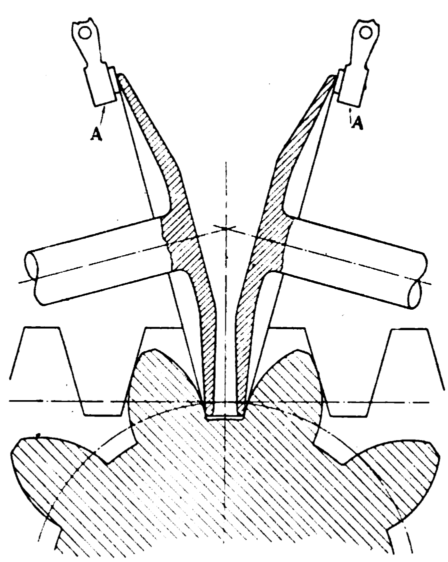

Fig. 1. Diagram showing the disked wheels used in Maag gear grinding machine.

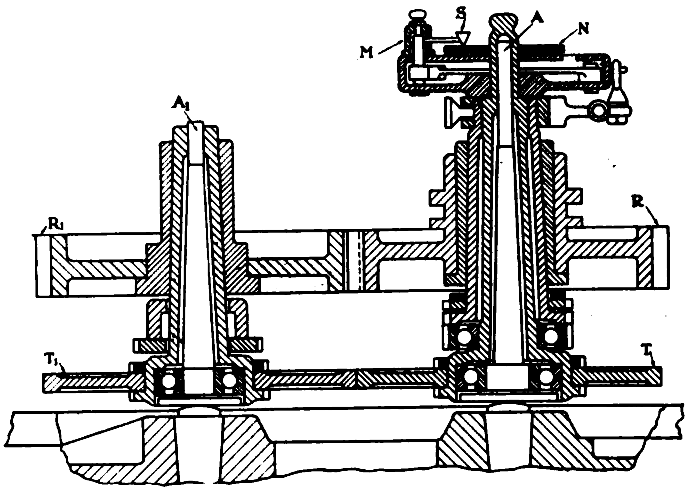
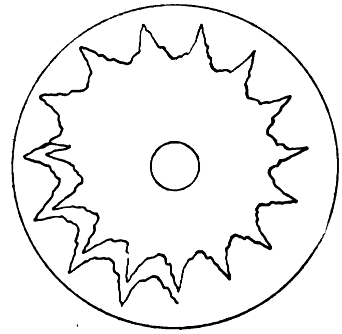
The interesting feature of the Maag grinding system is the means adopted for correcting for wear of the grinding wheels. It is stated that whatever wear takes place is evenly distributed over the cutting face of the grinding wheel, so that this face always remains plane and parallel to its original plane. The effect of wear is to reduce the width of tooth of the imaginary rack cutter and therefore to increase the thickness of the teeth being ground. The wear can therefore be compensated for by moving the grinding wheels apart, each parallel with itself.

The compensating mechanism consists of an electrically controlled mechanical device. For each grinding wheel there is a camshaft driven continuously at about 10 r.p.m. by belt and gearing from the motor driving the grinding wheel spindle. At each revolution the camshaft causes the lever A, Fig. 1, to oscillate on its pivot and to advance a diamond carried on its lower end toward the grinding wheel edge. If the movement of the lever is stopped by the edge of the grinding wheel at the correct point, nothing happens. But if the grinding lever has worn a certain amount the lever will swing far enough to establish an electrical contact. In this way an electric circuit is closed and the current flowing in this circuit is relayed to operate a clutch on a continuously driven shaft, from which, when the clutch is in, motion is transmitted through a pawl and ratchet wheel to a differential thread and thence to an adjusting screw on the grinding spindle bracket. By this means the bracket is moved until the grinding wheel lip plane is restored to its correct position. It is





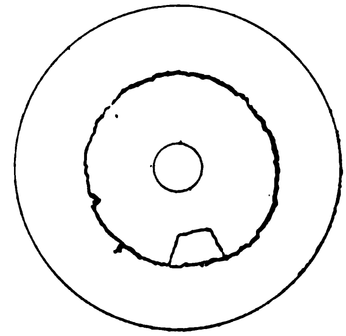


Fig. 3. Fig. 4.
Diagrams made by Saurer gear testing device.

Fig. 2. (Left) Saurer gear testing device used by Maag for gear inspection.

claimed that this adjusting mechanism is sufficiently sensitive to permit of an accuracy of the order of 0.001 mm. The mechanism, moreover, is said to be so trustworthy that it can be relied upon to keep the softest grinding wheel in adjustment. This allows of the use of relatively soft wheels, which, while wearing faster, cut more rapidly.

The adjusting mechanism is also used for setting new grinding wheels in the correct position. With the grinding spindle running, an electrical contact is made to bring the compensating mechanism into action. The adjusting screw then moves the spindle bracket until the wheel reaches its correct position, when the diamond carrying lever is forced back by the edge of the wheel sufficiently to break the contact and stop the motion. Electric current for the compensating mechanism is supplied by a two-cell storage battery.

Another interesting feature of the Maag gear grinding machine is the method by which the correct rolling motion of the gear during the grinding operation is obtained. The gear must, of course, be fed in an axial direction in order to grind the whole length of the teeth. Reliance is not placed upon a separate feed for the rolling motion, but, instead, rotary movement is imparted to the gear simultaneously with the axial movement by means of two steel ribbons, one end of which is fixed to the bed of the machine while the other is caused to unwind from or onto a segment secured to the work spindle and having a radius equal to that of the pitch circle of the gear being ground. Nine sizes of pitch blocks, covering the range of pitches in most common use, are supplied with the machine. Other pitches than those covered by these blocks can be cut by using the nearest size block and moving the stay carrying the fixed end of the ribbon by power at the requisite rate to give the difference of the motion.

For inspecting gears, Maag makes use of a very sensitive testing device developed by the firm of Adolph Saurer of Arbon, Switzerland (well known as truck manufacturers). A sectional view of this device is shown herewith. To determine possible inaccuracies of the gears the wheels R and R_1 are set on studs A and A_1 of the gear testing device and are slowly turned by hand. A friction wheel T_1, located upon stud A_1, is rigidly secured to wheel R_1, and carries along friction wheel T. The shaft of the latter is free to rotate in the wheel R, and is connected to the indicator disk N of a registering device M, the pencil S of which, through the intermediary of a system of levers, is connected to wheel R. If the teeth are cut perfectly, the pencil describes a smooth spiral line. But in case of defects the resulting tangential displacements between the absolutely uniformly rotating friction wheel T and the toothed wheel R are registered by the pencil on a scale enlarged about 200 times. By observing the wheel while turning, it is an easy matter to determine the location of defects and their nature.

The device can also be used in order to check the roundness and tooth clearance. By means of suitable bushings the wheels are placed upon the studs A and A_1, and with the hand wheel R and a scale they are set to the desired center distance. If now the two wheels are turned by hand, the feeler lever device, which is connected by means of links with A and A_1, shows how much the wheels deviate from cylindricity. Each division of the gage corresponds to a deviation of 0.01 mm.

If the hand deflections are repeated uniformly for each tooth, the fault lies with the tooth form. The clearance can be determined by multiplying the movement of the gage hand by twice the tangent of the pressure angle.

The two diagrams, Figs. 3 and 4, were made by means of this instrument. Fig. 3 is from a gear with inaccurate tooth form, which causes periodic fluctuations clearly shown by the diagram. Fig. 4 is from a gear with very accurate teeth. The sharp deflection of the indicator hand at one place is due to a human hair being placed between the teeth of the mating gears and the slight deflection at another point is due to a speck of dirt on one of the gears.

A Treatise on Gasoline and Other Motor Fuels

A VOLUME of some 700 pages entitled Gasoline and Other Motor Fuels by C. Ellis and J. V. Meigs, recently published contains much information of value to refiners and others interested in the chemistry, production, testing, mixing and use of liquid hydrocarbon fuels. More than twenty of the 27 chapters are devoted to description and comparison of cracking processes, but the remaining chapters deal at length with mixed fuels, fuel testing, refining methods and practice, benzol and alcohol as motor fuel, and shale as a source of motor fuel.

The authors of the book are chemists, and the volume naturally deals with the subject quite largely from the chemists' standpoint, though it contains much information bearing upon engineering and refinery practice and should prove of interest to automotive engineers who desire a knowledge of the characteristics of the various motor fuels, and the methods by which they are produced. The volume is well indexed and contains bibliographies of the subjects treated. The appendix contains much tabular information on the production and the physical and chemical characteristics of petroleum products. The book is published by the D. Van Nostrand Co.

A Production Manager's Solution of the Labor Problem

Production is largely dependent upon the men who operate the machines. A production manager recently outlined his practical ideas in an informal interview. His opinions show clearly how very closely related are low unit production cost and effective mental and physical workmanship.

By Norman G. Shidle

UNSTABILITY of employment is one of the biggest problems confronting American industry to-day, according to the general manager of an important automotive manufacturing plant. He believes, also, that the actions of employers at the present time in regard to their workmen will be of vast importance in determining the future trend and possibilities of industrial development. The plant operated by this executive employs several thousand men and is situated in a large urban district which was visited with the many labor troubles common to the war period.

The ideas on industrial relations held by this man are the result of many years of actual experience in production work. He holds his opinions regarding labor because, as he put it, "such methods pay a profit in better production and lowered costs." This indicates that he approaches the problem from a practical production standpoint and that he is not concerned with philanthropic motives. For this reason an outline of his methods and ideas should be of very practical value to other executives of the industry. This article summarizes an interesting conversation with this executive.

Unstability of employment is an extremely important problem, not only to the workman, but to the employer as well. Workmen are often blamed for holding back on production; for trying to avoid working themselves out of a job. It is easy to point out to the worker the bad economics of such procedure, but it is difficult to show him where his next week's wages are coming from.

The facts show that the workman has been urged to produce to his utmost one week and then been thrown out of work the next. It is not fair, and the best production cannot be expected from any man who is not certain as to whether or not his job will be good a week or two hence.

You ask me the question, "What is the solution to the problem of unstability of employment?" I don't know. I wish I did. The facts of the case are before us, however, and the vast importance of the problem must be recognized and all must aid in studying the matter.

The individual employer may mitigate conditions to some extent. We have tried to do that here. We have used every possible device to keep our old men at work. We have swung them from one kind of job to another. We have put them at work on a lathe one day and at pushing a truck the next. In this way we have kept as many at work as possible. A few of them didn't like being changed around at first. So I called them into my office here and talked to them. I told them why they were being shifted. I told them that I was striving in every way to keep them at work; to hold a job for them.

Then I pointed out the fact that when they got through being shifted around they were going to be bigger and better men. That in their particular case, the industrial depression was giving them a chance to learn more, to vary their experience, and to come through with a broader knowledge of the plant, its methods and organization. And what I told them is true. They will be better men—for themselves and for our organization. Even though a particular man on a particular day may not earn what we give him, he will earn it in the long run. Through this shifting around he will be worth more to us. We are making a virtue of necessity and will profit thereby in dollars and cents.

Better planning and more consideration for other organizations by our customers would help the situation a lot. And we are in the same position as many other plants. We make a large unit and are equipped to meet big production needs. Some of our customers do not think anything of sending us a telegram in the midst of a 500-a-week production telling us to stop production until further notice. Take a specific instance which has just occurred.

Two weeks ago one of our largest customers asked us to stop production for a week, and then to resume production last Monday. We laid off a number of men and told them to come back the beginning of this week. The men came back, but our customer changed his mind again and has delayed production indefinitely. We are running now simply on the hope that the customer will reinstate his order to go ahead within a few days.

We had promised those men work at that time. Had we not done so, they would have been free to look for other jobs. We had a real obligation to provide those men with work for at least a limited period after having made that promise. And we are making good. Had we failed to do so, we could not expect the workmen to believe us the next time we told them anything. The man that sends the telegram canceling orders usually considers the matter only from the financial standpoint. But he is having a direct permanent, as well as temporary, effect on the problem of human relationships in industry.

Better planning, better sales analysis and better scheduling of merchandising possibilities and probabilities will have a definite effect upon this big problem of unstability of employment.

Present Attitude to Labor

Right now is a very important time in the development of industrial relations. Labor was undoubtedly arrogant during the war; its newly acquired power went to its head, and in many cases workmen talked and acted in an unreasonable manner. Now the situation has changed. Many manufacturers are "taking it out" on their workers. There are plants within two blocks of here that are squeezing the blood out of their workers right now. Many others are taking this chance to get back at labor.

Any employer who adopts this policy of "taking it out" on his workers at this time is merely lowering himself to the level of the arrogant labor leaders whom he professes to despise so much and whom he says are unintelligent. He not only degrades himself in this way, but he lays up trouble for himself and his fellow employers in the future.

Even enlightened self-interest indicates that this is the time for the manufacturer to get the loyalty of his men, treat them fairly and gain their co-operation by exercising a justice of spirit and action that the labor leaders have not seemed able to understand. You don't have to treat labor right at this time, but for that very reason you will gain greater results by so doing.

The Individual Worker

Besides these general factors, however, there are important individual factors to be considered within every plant. The most important is that of making the man like his job. If I can get a man to like his job, I never have to worry about production. To accomplish this means attention to every individual worker. Many small factors of tangible and intangible character affect the situation in any given case. What these factors are and what is their relation to one another cannot be definitely stated. To discover them, however, constitutes another of the major problems before industrial managers.

Comfortable working conditions will help and should be provided in so far as possible. The psychological factors must also be considered. We had a department in which the men were laying down on the job because they felt that they would be out of a job as soon as the one was finished on which they were at work. We told them there was more work, but we couldn't convince them. I didn't blame them much, as most of them had been fooled elsewhere. Then I told the foreman to get the material for the next job and pile it up in the end of that department, where the men could actually see the advance work before them. He did this, although the new material wouldn't be needed for a week, and there was a definite increase in production the next day.

Then there is the matter of developing leaders. The foreman is, perhaps, the most important link in the management chain. I find that many men promoted from the ranks to foremanship cannot stand prosperity. Authority goes to their heads. I like to give a foreman as much authority as possible, but only in a few cases can much be given them, as the average foreman is likely to exceed his authority. Still it is the problem of the executive to train foremen for responsibility.

I happened to be going through the shop this morning, for instance, and I heard one of our foremen "bawling out" one of his workers at the top of his voice. He called him everything under the sun.

Just before you came in I had that foreman in here. I talked to him straight from the shoulder. I called him everything under the sun. He became angry. I meant that he should. Then I said, "You're sore, aren't you? But you had every bit of it coming to you. Don't you think Jones was sore out there this morning when you bawled him out before the whole department?

"The only reason he didn't step out and hit you be tween the eyes is that he was afraid he'd lose his job. He has a wife and several kiddies at home, and he doesn't dare take a chance on his job at this time. You made him lose his self-respect. Why don't you talk like that to other foremen? Because you know they wouldn't stand for it; they'd lay you out flat before you got half of it out of your mouth. You are simply a coward to talk that way to a workman whom you know can't hit back. This is your second offense, and there won't be any third. . . ."

And that is the only way to talk to a foreman of that kind. Workmen must be lead, not driven. Only in this way can they be expected to put that spirit into their job which produces the best quantity and quality results. Men who are driven can never be developed into leaders, and it is leaders that are greatly needed in our industrial organizations.

Too many men have a tendency to get into a rut and stay there. It has been my experience, which may not coincide with that of all others, that many men like to get on a single job and stay there. It is always a question, of course, whether the job dulls the man's mind and makes routine acceptable, or whether the mind was originally dull. Whichever may be the case, it is undoubtedly true that each job must be thoroughly understood if the best results are to be obtained from the worker.

An incident occurred here the other day which illustrates this point. There is one man whose task it is to hammer a rivet on a certain part of a body. He has been doing that job for several years. Recently the design was changed slightly in such a way that this rivet was placed one inch higher than previously.

It sounds almost absurd to say it, but that man found it almost impossible to adjust himself to striking that piece one inch higher. So mechanical had the operation become that he automatically struck the piece in the old place. The foreman kept close tab on him, but he continued spoiling piece after piece. Finally I went down and put under him a square piece of board one inch high. Standing on that board and striking as usual, he is now getting along all right.

These thoughts, expressed by a man skilled in production methods and experienced in handling men, are worth serious consideration. The incident just cited of the man striking a rivet illustrates the great lengths to which monotony work may go. It illustrates in a somewhat extreme manner the general tendency of all such work and indicates the tremendous problem which faces industry in this regard.

Such monotony jobs are multiplying rather than decreasing in industry. Their effect on the human mind is indicated by this example. It is inconceivable that means of remedying this situation shall not be found. Undoubtedly a long period of careful study and thoughtful experiment will be necessary. But the problem is the most important one which faces industry. And it is a problem of studying the individual worker.

Such individual studies far outrank in importance the more common investigations dealing with more general problems. The general studies are more usual, probably because they are easier to make, but the results obtained are not as permanent nor as useful. Practical production men are coming to recognize this fact more fully.

Government Data Helpful to Automobile Industry

At a recent meeting with a committee representing automobile manufacturers, Secretary Hoover indicated his desire to have the opinion of the industry as regards the figures which might be supplied by the Department of Commerce. The letter in this article answers that request.

RECENTLY a committee representing the automobile industry met with Secretary Hoover to discuss the gathering of data that would be of value to industry. Mr. Hoover said at that time that he was quite willing that the N. A. C. C. should be the chief agent in gathering statistics and that he had no desire to force figures from the industry. He also expressed a desire to know what figures might be compiled by his department that would be of value to the automobile industry. At Mr. Hoover's suggestion a list of such data has been prepared. This list is included in the following letter written to Secretary Hoover by Alfred Reeves, General Manager of the N. A. C. C.

AT the suggestion of Mr. J. Walter Drake, the chairman of the committee appointed by the National Automobile Chamber of Commerce to co-operate with you, we are specifying some of the data that the Department of Commerce might compile and that would prove most helpful to the motor vehicle manufacturers.

Trend of Business

In deciding on a correct production schedule, the manufacturer would be greatly aided by a report on general trend of business, which for the purposes of the motor vehicle maker, should include the following:

(A) Monthly pig iron production.
(B) Crop production in season compared with preceding years, with relative prices.
(C) Monthly advance orders on steel.
(D) Income tax statistics for latest preceding quarters, classified as to number of persons in various income groups in each State.
(E) Monthly railroad passengers and passenger-miles, also freight tonnage and freight ton-miles.
(F) Sales of packing-house products, shoes and textiles by months.
(G) Production, consumption and reserves of gasoline by months, compared with preceding years.

Much of the above material is separately available, but its consolidation in a single report would save individual labor and give a good index of general business conditions.

Car Uses

A report is now in course of preparation on the use of automobiles and trucks on farms and will be made part of the farm census. Similar investigation, but relating to economic uses of motor vehicles in other fields of work, would be most welcome.

Export Statistics

Manufacturers would be interested in export statistics of motor vehicles so classified as to differentiate between different priced passenger cars and motor trucks of different capacities.

At present these figures are grouped according to COMPLETE MOTOR VEHICLES and CHASSIS and specified by NUMBER and VALUE.

The classifications more suitable to the manufacturers in gauging their percentage of foreign trade should be as follows:

COMPLETE PASSENGER AUTOMOBILE OR CHASSIS

Costing up to $800 inclusive		From $801 to $1501		From $1501 to $2500		From $2501 to $3500		From $3500 up	
No.	Value	No.	Value	No.	Value	No.	Value	No.	Value
..	..	..	..	..	..	..	..	..	..

COMPLETE MOTOR TRUCKS OR COMMERCIAL CHASSIS

Up to ¾ ton inclusive		From 1 to 1½ tons		From 2 to 3 tons		From 3½ to 5 tons		From 5½ tons and up	
No.	Value	No.	Value	No.	Value	No.	Value	No.	Value
..	..	..	..	..	..	..	..	..	..

Foreign Production and Prices

Especially interesting to the American manufacturer would be definite data on the production, specifications and prices of cars made and sold abroad in competition with the U. S. product, also the number of workmen employed in the various foreign motor vehicle factories.

Re-Imported Cars

Because re-imported American automobiles and motor trucks have a direct bearing on the domestic as well as foreign markets, it would be helpful if the Department of Commerce were to issue monthly statistics on the extent of this trade. Two statistical groups would be sufficient for this purpose and would show the number of American passenger cars and motor trucks that were originally part of the U. S. war equipment, then sold to the Allied Governments, and are now being re-imported into the United States.

Uniform Statistics

It is desirable to have a uniform method of classifying statistics of motor vehicle exports from principal manufacturing nations. If England, France, Belgium and Switzerland could be induced to compile their monthly export statistics according to passenger cars and Commercial trucks and specify by number and value as is done by the other manufacturing nations, it would be easier to determine the world-wide movement in motor vehicle trade.

Promptness Essential

The value of these reports to the manufacturer depends solely on the promptness with which they are issued. Emphasis is put on this point in full realization that the Department of Commerce was inadequately supplied with funds necessary to carry out the work effectively.

The foregoing suggestions as to means in which the Department of Commerce can aid the automobile industry relate solely to statistical compilations. There are numerous other ways in which the Department can be helpful to our industry and concerning which we shall write later and thus avail ourselves of your courteous offer of co-operation.

Government Helps to Build 22,030 Miles of Highway

On March 1 of this year 22,030 miles of highway, extending into every State, had been completed or were in process of construction, says the chief of the Bureau of Public Roads, United States Department of Agriculture, at a total estimated cost of $361,946,868. The percentage of this total estimated cost which will be incurred for each type, and the mileage of each type, based upon the records of plans approved, are as follows:

Per Cent and Mileage of Each Type of Road:

	Per cent of total estimated cost.	Mileage.
Type 1, including earth, sand, clay and gravel	32.2	15,300
Type 2, including water bound and bituminous macadam	9.0	1,530
Type 3, including brick, bituminous concrete, Portland cement concrete	48.8	4,890
Miscellaneous	4.0	310
Bridges	6.0	...
	100.0	22,030

The states initiate the road projects, but before Federal aid is granted an engineer of the bureau makes an inspection of the roads to be improved, studies the local conditions, consults with the State highway department, and no projects are approved which are not considered suited to the conditions to be met. Many popular fallacies exist as to road improvement, and there have been many misconceptions as to the types of roads on which Federal aid funds may be used. Properly built earth roads, say specialists of the department, are the fundamental requirement in all highway improvement. Regardless of the material or type of surfacing which is to be placed, the preparation of the roadbed requires the highest engineering skill and experience. The department considers that the use of adequate sums for the securing of proper location, thorough drainage, permanent bridges and culverts and the elimination of railroad crossings is demanded if enduring improvements are to result.

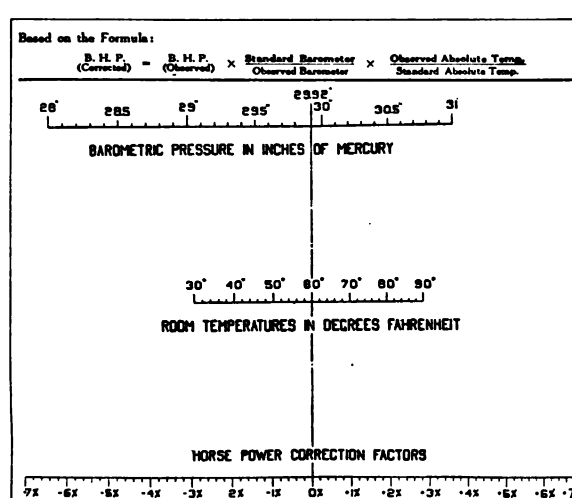
Federal aid is allotted to the improvement of earth roads, but only with the stipulation that a suitable surfacing will be placed as soon as funds become available. This allows the roadbed to be prepared and become thoroughly consolidated before the surfacing is placed, which is highly desirable from a construction viewpoint. To follow such a course, however, is out of the question when a road is heavily traveled and some form of surfacing must be provided. To care for traffic under these conditions, frequently a sand clay or gravel surfacing is provided, which will serve for several years and yet allow the road to be maintained under reasonably heavy traffic.

Horse Power Correction Alignment Chart

An alignment chart designed to afford a ready means of determining the correction factor for bringing dynamometer test data to a common basis of air temperature and barometric pressure has been published by the Zenith Carburetor Co. This graph allows of a direct comparison between runs made under different atmospheric conditions. It is based upon the assumption that brake-horsepower at full throttle varies directly with the atmospheric density, and is computed from the formula which appears above the chart. The standard barometer is taken at 29.92 in. of mercury and the standard temperature at 60 deg. Fahr. The absolute zero of the temperature scale is taken at minus 459.5 deg. Fahr.

To use the chart, a straight edge is placed on the graduations of the barometric pressure and room temperature scales corresponding to the observed pressure and tempeature during the test. The point where this straight edge crosses the lower scale gives the correction factor in per cent, plus or minus. If the sign is plus, the correction should be added; if minus, it should be subtracted.

For example, for 29.80 inches of mercury barometric pressure and 46.0 deg. Fahr. temperature, the correction factor is minus 2.3 per cent. Assuming that the dynamometer balances at 108.7 lb., the correction is 2.3 per cent of 108.7, or 2.5 lb. Subtracting 2.5 from 108.7 gives 106.2 lb., the corrected pull. It should be noted that the correction factor is equally applicable to torque, brake horsepower and mean effective pressure.



1—Zenith alignment chart for dynamometer, torque, and brake horsepower correction factors for standardization of engine test data.

Sales Charts Based on Average Life of a Vehicle

The charts presented here depict in graphic form the various points discussed in an article concerning the average life of cars published recently. The semi-logarithmic scale used in some of these graphs shows clearly both the actual and relative values of the various factors involved.

Charts by W. C. Marshall

TAKING into account all the factors involved, P. M. Heldt presented an analysis of the average life of cars and trucks in AUTOMOTIVE INDUSTRIES of March 17, 1921. That article took the yearly production, registration and export figures and with them as a basis computed the average life of cars and trucks during the last seven years.

Production figures were available from 1905, but registration figures were available only from 1912, when AUTOMOTIVE INDUSTRIES first began to compile them. With these figures as a basis, the average active life of a car was determined at 5.3 years.

This article proceeded purely upon the discussion method, the results being reasoned out and presented in logical sequence. There is a definite advantage, however, in bringing out these various points by graphic means to show more clearly the relation between the various factors and to form a basis for extending the ideas for future probabilities.

The accompanying charts fulfill this purpose. They were prepared by W. C. Marshall on the basis of the figures in Mr. Heldt's article. They show in an interesting way the comparative relationship between the various factors involved.

It is not necessary to go into a detailed discussion of the various charts since the individual purpose of each one is definitely stated in the caption. Some of the data is plotted on regular rectangular coordinate paper with regular spacing between the lines, while others are plotted on a semi-logarithmic scale.

This latter method has distinct advantages in showing relative gains or losses and in indicating the true relative

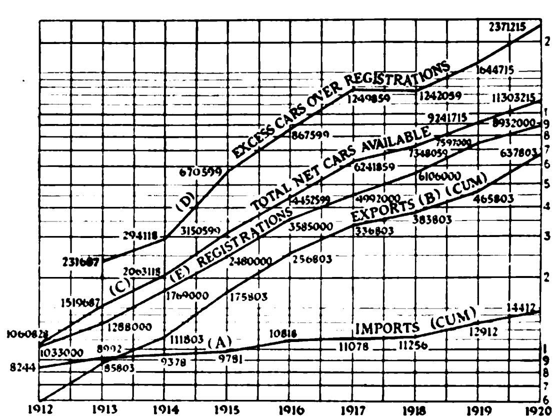


Chart 1 is a plot on semi-log paper of (A), the imports of cars beginning in 1912 with the total sum for the years 1906-1912 inclusive equal to 8244. The cumulative curve of exports beginning with 2200 in 1906 is shown by curve (B). The number 58,914 plotted for 1912 is the total number exported up to Dec. 31, 1912. The cumulative number to Dec. 31, 1920, is 637,803. Curve (C) is a cumulative curve of cars manufactured plus the imports minus the exports. This is called the net prod. The number 1,060,828 represents all the cars available in the U. S. up to and including 1912. The total at the close of 1920 is 11,303,215. Curve (E) shows the cars registered each year and is not cumulative. Curve (D) shows the excess total cars made over the registrations. This chart shows by the slope of the lines the percentage increase over that of the previous year. Parallel lines in different curves show the same rate of increase or decrease and can be readily compared.

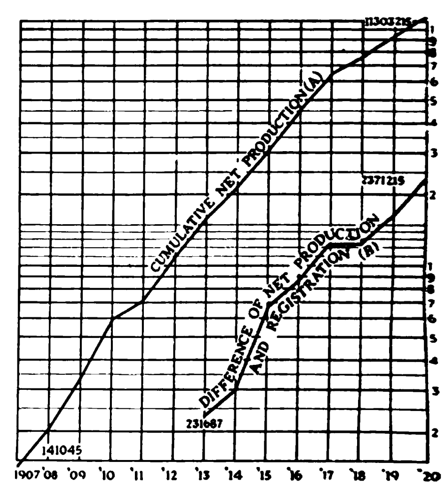

Chart 2 (right) plot on semi-log paper of (A) the total production plus imports minus exports and is cumulative. Curve B shows the excess of cumulative available production plus imports minus exports, over registrations. By running back horizontally to curve A and measuring the intercept between the two curves A and B we find the average life of cars up to the year taken on the B curve and the year at the bottom of the chart below the intersection on the A curve which shows the date of manufacture of the oldest cars in service in the year taken on curve B

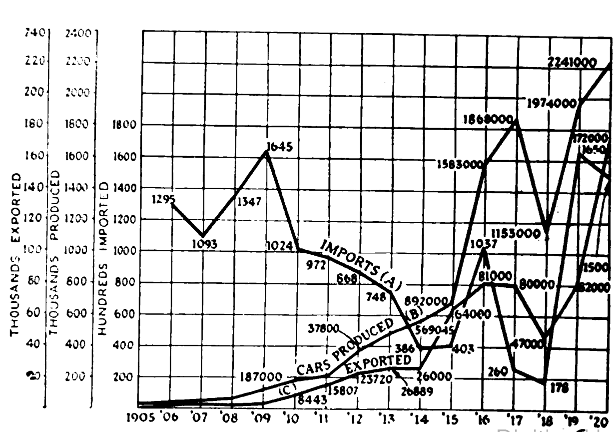

Chart 3 (left) shows fluctuations in yearly production, imports and exports from 1906 to 1920. This shows the marked decrease of imports in 1914 and 1915, 17 and 18, the increase in exports in 1920, and the increase in manufacture in 1917 and 19, as well as the slump in 1918. The last year of the war shows the most marked decrease in production, imports and exports, and the year following the greatest increase of all three

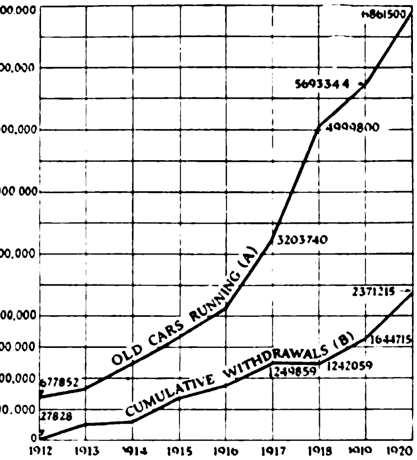

Chart 4—Curve A shows the old cars in service each year. The increase yearly is quite marked from 1916 to 1918, and drops off in the following years. Curve B shows the total number of cars withdrawn from service due to old age and storage causes. It is a cumulative curve. From 1919 to 1920 shows a marked increase in number over any preceding year.

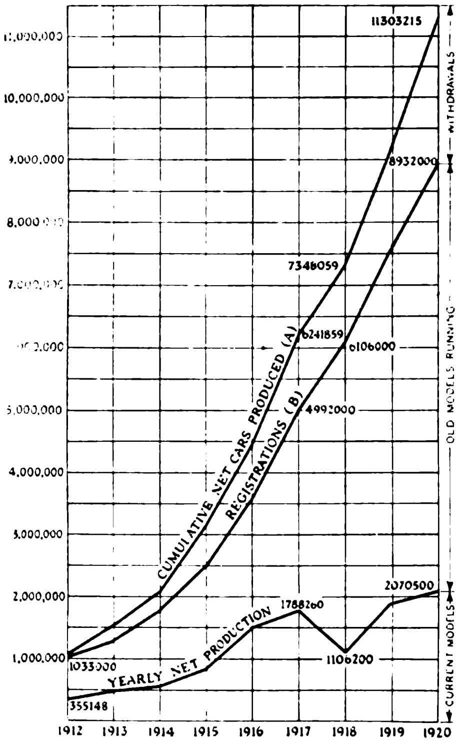

Chart 5 shows the cumulative net car production since automobiles were first manufactured and the B registrations each year from 1912. The difference between these curves each year shows the cars withdrawn from service that year. The net yearly production curve C shows how many of the registrations are new car owners. The difference between the registration B and yearly production curve C gives the old cars running.

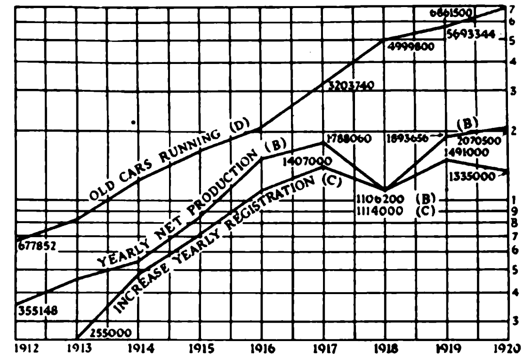

Chart 6—This chart is plotted on semi-log paper, the slope of the lines showing the percentage increase of each item. Curve D shows a pretty uniform per cent increase, except from 16 to 18, when it increased much more than any other period. At the same time the per cent of cars produced fell off as well as the percentage of registrations. These two decreases affected the use of old cars by causing the owners to use them a year longer than they ordinarily would. 1919 shows the per cent of old cars to have decreased and the per cent of production and registration to have risen again nearly to normal

value of the various sets of figures. It differs from the full logarithmic paper in that only the vertical coordinates are plotted logarithmically, while the horizontal coordinates are arithmetical.

An interesting discussion of the advantages of this semi-logarithmic method of charting is given by W. C. Brinton in his volume on "Graphic Methods for Presenting Facts." Part of this is worth quoting here:

"The principles involved," Brinton says, "are the same as those embodied in the slide rule. . . . No matter what the location of the chart, if the logarithmic spacing is used in the ver-

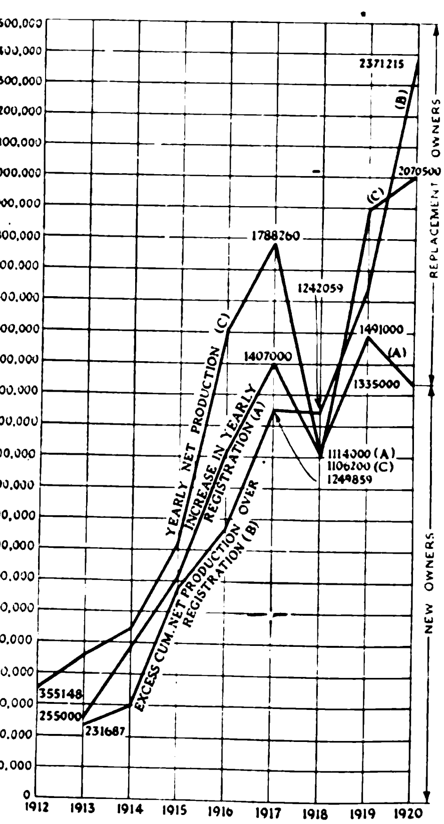

Chart 7—Curve A shows the variation in registration from year to year. Curve B shows how the total production of cars varied in excess of the registrations each year. As this excess is made up of new car owners and replacement owners, the increase in registrations is due to new car owners, and the difference shows the old cars which have been relegated to the scrap heap. The yearly production curve C shows the great falling off during the last year of the war, with resultant increase the following year.

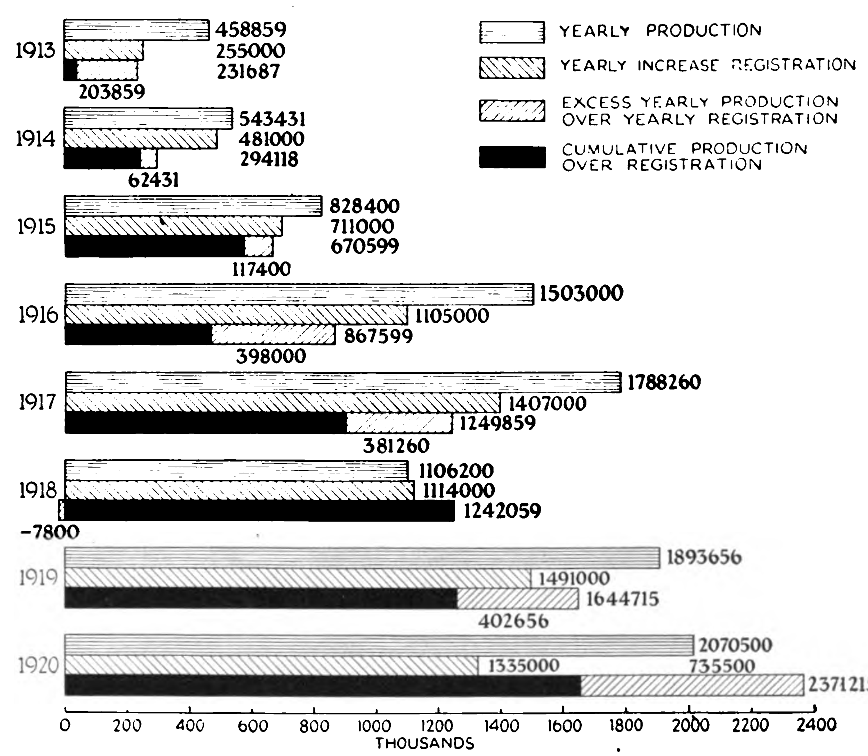

Chart 8 is a barograph showing the relation between yearly production, yearly increase in registrations, excess of production over registrations and total number of cars withdrawn since the period of automobiles began. The shaded portion at the end of the last-mentioned bar represents the number of cars withdrawn during that year. The standstill of the whole industry is brought out very plainly by the shortening of the bars during the year 1918, except the bar representing cumulative production over registrations and the number of cars withdrawn, which disappears entirely and even becomes a minus quantity, showing that all the old cars in storage and the ones barely able to run were gotten out and made to go through that year.

tical scale for curves, the angle of the upward or downward inclination is the same for all curves affected by the same percentage of change. . . . The logarithmic scale permits the exhibition of both actual and relative values and actual and relative fluctuations.

"It is unfortunate that there is so much difficulty in obtaining paper having logarithmic ruling in one direction and arithmetical ruling in the other direction. The arithmetical ruling is essential in statistical work, since we ordinarily must plot as one scale data representing years or other subdivisions of time. In statistical work we cannot well use a paper having logarithmic ruling in both directions, yet that is the only kind of logarithmic paper which can be obtained in most stores selling drawing materials and engineering supplies."

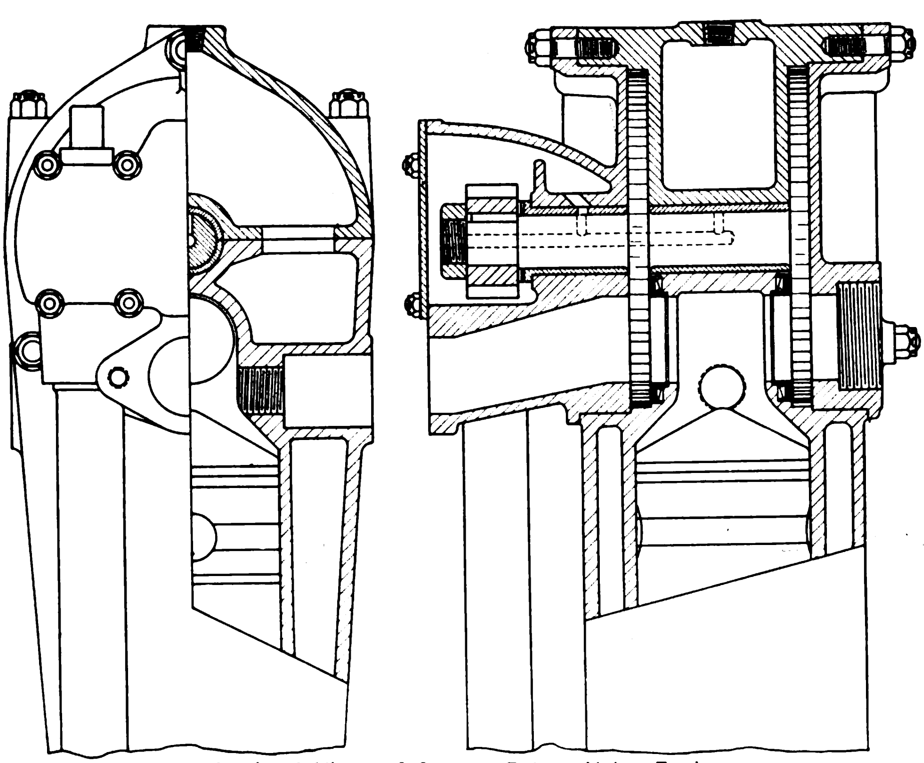
From this discussion it is evident that this sort of chart is particularly adapted to the material presented.

The value of the charts lies largely in the possibility of prejudging future trends on the basis of past performances as shown. Some such attempt was made in the charts recently shown prepared by the Commercial Research Department of the Franklin Automobile Co. A study of the charts shown here, however, will bring out certain different points, while future prediction can take into account current business and economic conditions as well as theoretical projection of the curves.

A New Rotary Valve Engine

A RATHER unusual type of rotary valve engine has been designed by H. P. Stevens. In order to develop some of the details of the valve mechanism in an experimental way, Mr. Stevens built a single cylinder upright engine, and two sectional views of the upper part of this engine are shown herewith. The compression space is in the head and is of inverted U-section with flat end walls which contain the inlet and exhaust ports. The valve functions are performed by two large diameter disks, both on the same shaft, the disks being located on opposite sides of the compression chamber. In order to get the two disks with their shaft into position, the upper part of the cylinder is split through the valve shaft axis. Each of the disks has a port cut in it, and when this port comes opposite the port in the compression chamber wall, intake or exhaust takes place. The valve shaft is rotated at uniform speed by means of a vertical shaft and helical gears, consequently, the valve mechanism is practically noiseless. The two valve disks are backed up by the circular end plates which contain the passages to which the inlet and exhaust pipes are secured and one of which also carries a bearing for the valve shaft.

The spark plug is screwed into the combustion chamber wall between the two valve disks. It proved a difficult problem to seal the disk valves, but a form of sealing ring is said to perform this function effectively. These rings are set into ring grooves in the valve seats surrounding the valve ports therein. Another important problem in connection with an engine of this kind is the lubrication of the valve mechanism. In the engine here shown this is effected entirely by pressure. In a four-cylinder engine with this valve construction it is necessary to cast the cylinder head separately and split it through the valve shaft axis.



Sectional Views of Stevens Rotary Valve Engines

Measuring Surface Tension

THE common method of determining surface tensions, by means of capillary tubes, is subject to the disadvantage that long capillary tubes of uniform bore are hard to find as well as to keep clean; besides, the meniscus is subject to cooling which has a strong effect on the surface tension. A new method which overcomes these difficulties was described in two papers recently presented to the Faraday Society by Allan Ferguson and P. E. Dowson of Manchester College of Technology.

Instead of measuring the rise of the liquid, Ferguson and Dowson force the liquid down to the lower end of the capillary, dipping vertically into the liquid, and they measure the pressure required for this in a suitable manometer. The liquid is placed in a beaker resting on a movable table. The capillary tube, which is dipped into the liquid, may be short; it is fused to another glass tube leading over to a mercury bottle; by raising this bottle the air in the glass tube forces the liquid, which had risen in the capillary, down to the edge of the tube at the point where the meniscus is formed.

The actual measurement is transferred to a U-tube gauge, branched off from the horizontal portion of the glass tube. Very concordant results have been obtained by this reversed method, and the fact, noticed by Ferguson, that benzol gave a surface tension of 29.6 dynes per centimeter when examined immediately after purification, but a higher value (29.9) after a day or so, testifies to the delicacy of the method.

Benzol is hydroscopic and increases its surface tension by absorbing water.

Manufacturing as Well as Statesmanship Subject to Impractical Idealism

The manufacturing organization should be thoroughly sold on the merits of the product, but it should temper its enthusiasm for perfection with an understanding of practical production methods and possibilities. Co-operation saves money. Some actual instances are related here.

By Norman G. Shidle

THE final success of an automobile concern rests upon the selling of its product. The real opinion of the car held by members of the manufacturing organization, however, is an important factor in contributing to that final success. Most manufacturers have realized the importance of this and the visitor to almost any automobile plant finds the entire organization thoroughly sold on its product. This is as it should be, but moderation is desirable.

Statesmen and writers have been accused by business men of "impractical idealism." There is such a thing as impractical idealism in the manufacture of automobiles as well. Enough is as good as a feast. It is well to imbue the manufacturing organization with the necessity for perfection, but care must be taken to provide that all the members of that organization recognize what is perfection and what is not; that they understand the practical limitations of manufacturing processes as well as the theoretical elements of automobile design.

An incident occurred recently in connection with a certain car that illustrates to some extent the dangers of an "over-sold" manufacturing organization. The body for a new model was designed. Presumably all the factors of body and chassis construction were carefully considered before the design was completed and the finished drawings were made ready for production. Much of this body was to be made of pressed metal and the construction of expensive dies was necessary.

The drawings were submitted and the dies made up by an outside concern. Production was about to begin, when the manufacturer decided on certain minor changes in body design. The expensive dies had to be altered. Production was started finally, but still further changes were desired by the manufacturer. Production was delayed and the expensive dies were altered again. Probably these changes in design were deemed necessary by the car manufacturer in his effort to make a car "just a little better" than that of any of his competitors. Yet the changes did cost money, and to some whose long experience might constitute them competent judges, they did not seem in keeping with the increased cost.

Another instance of similar nature occurred when a certain car manufacturer was equipping part of his product with disc wheels of a standard make. The inspection department of the car manufacturer complained continually concerning the quality of fit of certain bolts on the wheels. Finally the engineer of the wheel maker journeyed half way across the continent to the car manufacturer's plant. The inspection man objected that the bolts in question did not fit snugly and perfectly and desired certain changes in design.

The wheel engineer stated that this was the standard wheel that was being made in quantity and that any change in design would greatly increase the cost. He explained, moreover, that the bolts in question would fit properly when an inflated tire was placed on the wheel. The inspection man said they would not. The wheel engineer suggested that the experiment be tried to prove his statement. The inspection man said that it would be useless to do that since, the pressure of a tire would not force the bolts into their proper place and refused to make the experiment. He said that for this car the thing must be exactly perfect and that what might do for others would not do for them.

Just then one of the chief executives happened along. The wheel engineer explained the situation and again demanded that a test be made. The executive immediately acceded to his request. A tire was placed on the rim and pumped up with a hand pump. The bolts slipped neatly into their proper place and the wheel was shown to be perfectly constructed. Even then the inspection man objected that there was probably about 100 pounds pressure in the tire, which was more than the ordinary tire should carry. A pressure gage was applied, however, and showed the pressure to stand at 40 pounds.

Had it not been for the insistence of the wheel engineer, the entire shipment of wheels probably would have been rejected as defective and unfit for use. An organization, apparently green in the particular work, might have caused considerable trouble and expense to the company.

Other parts makers, as it happens, had similar experiences with this same organization. Pieces were rejected because of unimportant abrasions on unexposed surfaces, and for various other reasons, none of which had been discussed when the contract had originally been made. The result of such experiences is to generate some ill-feeling between the manufacturer and the parts maker and to increase the price which the manufacturer will have to pay for future orders of parts.

It is, of course, the undoubted right of the manufacturer to demand whatever quality of work he desires, but there is a practical limit to what can be expected for a reasonable cost. This cost can often be lowered without impairing an essential feature of quality if the co-operation of the parts makers is solicited and a fuller relation of confidence is established throughout the operations.

Moreover, it is obvious that as the degree of confidence between the manufacturer and the parts maker increases the many petty irritations and difficulties will diminish. As suspicion decreases, minor troubles di-

minish in proportion. A big truck manufacturer, for example, was telling recently of the men which his organization maintained during peak production times in the plants of various parts makers. These men were there as inspectors and in some cases almost as directors on the manufacture of the parts. Every care had to be taken that defective material was not used and that the parts were up to standard.

"We also had a lot of parts made by the Blank Company," the manufacturer continued. "No," in answer to a question, "We didn't have a man there. We didn't need to. We have done a lot of business with them, we know them and they know us well, and we know that we can depend upon them to do the job in every way as well as it can be done."

Money can be saved by an increase in confidence and co-operation. Every manufacturer knows that it costs him more money per unit to deal with certain firms than with others even though the quoted price on the article be the same. Sometimes this is the fault of the parts firm. Sometimes, however, it is the fault of the manufacturer. The interdependency of the various units of modern industry makes co-operation a paying proposition and a practical necessity.

Restoration of Worn Machine Parts

A NEW process for building up worn machine parts, known as the Fescol process, is described in *Engineering*. The worn part is built up by depositing on it a coating of nickel of suitable thickness, and the treatment employed is said to give a coating so adherent that it is practically impossible to remove it from the core by any ordinary means. The process is due to R. J. Fletcher of London and has been in use for more than a year.

Parts such as crankshafts, spindles, axles, pistons and similar objects, which have been reduced in diameter or rendered oval by wear, can be made perfectly serviceable by depositing the nickel where necessary, keyways, screws and other parts on which the deposit is not required, being protected as will be explained later. Motor-car engine cylinders which have been scored by the wrist pin, and lathe leading screws badly worn in the working portion, are other examples of repairs satisfactorily effected by the process at a small fraction of the cost of replacement.

The metal deposited has good wearing properties, its Brinell hardness number, as determined by tests at the National Physical Laboratory, being about 360 when coated to a thickness of 0.04 in. on a steel with a hardness number of 298. The corresponding figure for the hardness of a mild steel having an ultimate tensile stress of 32 tons per square inch would be 150. The adhesion of the nickel coating is remarkable, a longitudinal pull of 11.95 tons having been found necessary to shear a ring of nickel 0.215 in. wide from the surface of a steel cylinder 1 in. in diameter, on which it had been deposited. These figures, which were also obtained from a test at the National Physical Laboratory, indicate that the adhesion amounted to 17.6 tons per square inch of adhering surface.

In working the process, the article to be treated is first placed in an alkaline electrolytic bath, in which all traces of grease are removed, and, after rinsing and drying, it is dipped bodily into a bath of molten wax. The wax, which rapidly cools when the article is lifted out of the bath, is then removed from those parts on which the deposit is required and left adhering to the other parts. The article is next placed for a few minutes in an acid electrolytic bath which removes any metallic oxides from the exposed surfaces, renders them chemically clean, and also brings them to a suitable molecular state to receive and retain the deposit. This acid bath is an essential part of the process, and is that to which the exceptional adherence is due. The nickel depositing bath, to which the article is then transferred, is of the usual composition, and is worked at a temperature of about 85 deg. F. The current density used is about 15 amperes per square foot, and, at this density, nickel is deposited at the rate of about 0.001 in. per hour, so that if a deposit 1/8 in. in thickness is required the article must remain in the bath for over five days. This slow rate of deposition is, perhaps, a drawback, but it could probably be improved by raising the temperature of the bath and also by agitating the objects while the deposition is proceeding.

Summary Concerning the Motorcycle and Bicycle Industry in 1919

A PRELIMINARY statement of the general results of the 1919 census of manufacturers with reference to the motorcycle and bicycle industry has been issued by the Bureau of the Census, Department of Commerce. It consists of a detailed statement of the quantities and values of the various products manufactured, prepared under the direction of Eugene F. Hartley, Chief Statistician for Manufactures.

Reports were received from 51 establishments engaged in the industry during 1919, with a total value of products of $53,105,995. At the census of 1914 there were 78 establishments with products valued at $22,234,262. Of special interest is the increase in the production of bicycles, the number reported in 1919 being 470,675, as compared with 299,029 in 1914, an increase of over 57 per cent.

In 1919, 9 establishments were located in Ohio, 8 in Massachusetts, 7 each in Illinois and New York, 5 each in Indiana and Wisconsin, 4 in Pennsylvania, 3 in Connecticut, 2 in Michigan, and 1 in Washington.

The statistics for 1919 and 1914 are summarized in the following statement. These figures are preliminary and subject to such change and correction as may be necessary from a further examination of the original reports.

COMPARATIVE SUMMARY OF STATISTICS FOR THE MOTORCYCLE AND BICYCLE INDUSTRY, 1919 AND 1914

	1919	1914
Number of establishments	51	78
Value of products[1]	$53,105,995	$22,234,262
Motorcycles:		
Number	59,214	62,154
Value	$16,176,055	$12,161,775
Bicycles:		
Number	470,675	299,029
Value	$12,277,341	$3,757,318
Tricycles, value	$625,522	
Motorcycle parts, including delivery and side car attach.	$10,646,480	$6,315,169
Bicycle and tricycle parts	$4,814,668	
All other products, including repair work	$8,565,929	

[1] In addition, in 1919, motorcycles and bicycles, including parts, to the value of $2,205,743 were produced by establishments engaged primarily in the manufacture of other products; in 1914, to the value of $4,647,798 by establishments of a similar character.

The FORUM

Four-Wheel Brakes Not Too Severe

Editor, AUTOMOTIVE INDUSTRIES:

I have been reading with a great deal of interest your various articles regarding the use of four-wheel brakes abroad, and have noticed in your issue of June 16 some letters on the subject from prominent American automotive engineers.

The first letter from W. R. Strickland, chief engineer of the Peerless Motor Co., headed "The Disadvantages of Four-Wheel Brakes," convinces me that Mr. Strickland has had no experience with a car on which the four-wheel brakes are properly designed. He states that it is very uncomfortable for the passengers when the car is suddenly stopped.

With the Delage, which is, of course, the only car I know anything about, I claim that there is a great deal less discomfort in short stopping than would be possible with any car having two wheel brakes only. As a matter of fact, there is practically no tendency to throw passengers forward.

We have demonstrated with one car upward of 24,000 miles. The original brake lining is still on the brakes and, as you probably know, were there any weaknesses in this braking system they would have developed long since. I can assure you that these brakes have been subjected to a great deal more strain than would be the case under normal conditions, and yet I claim we can stop this car in unusually short distances with a great deal less discomfort to the passenger than is possible under any other braking system.

A. A. ROST, President,
Delage Concessionaires (U. S. A.), Inc.

Factors Affecting Fuel Economy

Editor, AUTOMOTIVE INDUSTRIES:

The paper entitled Elements of Automobile Fuel Economy, by W. S. James, read at the summer meeting of the S.A.E., was so comprehensive in its nature that some of the salient points are likely to become absorbed without full appreciation. The average user perhaps does not realize that an expenditure of power, and consequently of fuel, is necessitated in order to drive a car on a bumpy road in excess of that required for a smooth road. The magnitude of the excess can be measured by the power required to accelerate vertically the mass of the unsprung weight and some proportion of the sprung weight, the number and distance of the accelerations per unit time being determined by the nature of the road surface. I have found that loss of speed of the car in a horizontal direction accompanied an increase in the number and amplitude of vertical motions imparted to the body of the car. By fitting suitable springing devices the energy previously expended wastefully was turned to good account.

Does not much of the fuel wastage in every day life result from driving cars and their occupants vertically as well as horizontally? I am sure of it. We have tables of road resistance such as are reproduced in Mr. James' valuable paper, but we would also like to have some definite data as to the effects of different types of springing upon fuel consumption.

I have measured the power expended upon propelling the various parts of the car body at different speeds and the resulting cost of using a wind screen, etc., in cents per mile.

These costs vary very considerably not only from moment to moment but from day to day.

Tests of one car I have made on the track show at 30 m.p.h. and different weather conditions a variation in resistance to car motion from 125 to 180 lb. For this reason it becomes difficult to make accurate deductions based upon road or track measurements, though they are sometimes helpful.

I cannot too strongly deprecate, as I have always done, the practice of some engineers of placing horsepower output on a pedestal and treating all other considerations as of minor importance. How often has the fact been pointed out that the maximum power is seldom if ever used, and that seldom is the test bench performance attained in ordinary usage due to many causes which need not be gone into here? Mr. James and Mr. Nelson have helped forward the argument in favor of giving a better consideration to the actual requirements in service. A great deal of time and effort is expended upon futile argument or upon the third place of decimals while there remain with us major problems the solution of which would help forward the objects of economy to a much greater extent.

If fuel were not so cheap, engineers and others would be more careful about how it was used.

R. W. A. BREWER.

Metal-to-Metal Clutch Lubrication

Editor, AUTOMOTIVE INDUSTRIES:

I have read with interest Mr. Chase's article on American and British practice in clutch design.

He is, however, in error when he states that clutches of the type shown in Fig. 18 as used on the Vauxhall car must needs be run in oil. The Vauxhall clutch has been in successful use since 1910, the only lubricant used being powdered graphite. For this reason the somewhat formidable list of disadvantages of this type of clutch presented by Mr. Chase. do not exist.

An additional advantage of the metal-to-metal disk clutch is that no provision need be made for adjustments of the clutch spring pressure, and as the total wear after prolonged use is negligible, there is also no necessity for providing any adjustment for the position of the clutch pedal itself.

LAWRENCE H. POMEROY.

The reference to the Vauxhall clutch as being one which runs in oil is evidently in error. It is true, however, that metal-to-metal clutches require lubrication, graphite being used in place of oil in this case, with consequent reduction in the coefficient of friction. For this reason a greater number of plates is required as compared to fabric-faced disks to carry a given torque with a given spring pressure and size of disk. The cost and the spinning weight are therefore higher, hence the metal-to-metal type is not without disadvantages. Some other makes of metal-to-metal clutches use oil for lubrication, and are subject to the other disadvantages cited in the paper referred to.—EDITOR.

Determining a Better Basis for Wage Payments

The American Federation of Labor has asked its executive council to attempt to determine a sound basis of wage adjustments. Service rendered by individual is only logical basis, but practical application must come slowly. Manufacturers should take up this problem.

By Harry Tipper

THE convention of the American Federation of Labor has brought forward many interesting matters for the man who desires information on the general ideas of the labor leaders prominent in that body.

The importance of the presidential honor in this organization is indicated by the fight which took place for a change in the situation. The character of the politics in labor organizations is indicated by the character of the campaigning and some of the statements that have been made regarding the support of the candidates.

The political character of these organizations is very definitely indicated in the suggestions of resolutions, in the actions of the various committees and in the attempt being made to have the American Federation of Labor lend the strength of its endorsement to proposed legislative matters, matters of international policy and matters of general political character.

For the industrial executive, however, the most important items are those dealing with the policy of the American Federation in regard to industrial matters.

One of these marks a departure from the usual program of this organization and is interesting because of its admission that the present system is not satisfactory. This refers to the method of fixing wages, and calls upon the executive council to investigate the manner in which wages are fixed with a view to getting a better basis than the cost of living for determining wage scales.

"Fixing wages by the cost of living," the executive council report said, "brings death through a perpetuation of a static condition." The object of this investigation is stated to be the discovery of "a sounder basis for our social life as a whole." Unfortunately, the American Federation of Labor is committed to uniform scales of wages, and the general tendency of the movement of trade unionism is toward uniformity all through the occupation, irrespective of local conditions.

The statement has been made in these articles that the cost of living is not a sound basis for the consideration of wages, and to this extent the investigation of the Executive Council of the American Federation is justified in its proposed examination. It is hard to see any possibility of a sounder method of adjusting wages, with the tendency definitely developed toward uniformity along these lines. There is evidence of an incomplete examination of the situation in the statement that wages are fixed on the cost of living, because this is not entirely true.

Wages have been fixed by the available "supply and demand," and, while they have a general tendency to agree with the reasonable requirements to maintain life, the particular wages in any occupation have been the wages which the manufacturer was obliged to pay, either because of the relation between supply and demand, or because of the power of the organized forces among the workers in that industry.

However, the fact that the American Federation of Labor is to conduct an investigation into wage systems with the idea of suggesting a sounder basis is quite important. It indicates the existence of general dissatisfaction among the leaders, not only with wages, but with the methods of computing wages.

Whether the conclusions arrived at are of importance or not, the investigation itself will undoubtedly suggest matters that will be of advantage to the industrial leader in his study of the wage question. Of course, the only logical basis for wages is the service rendered by the individual, and the relation between that service and the social advantage. There is no hope of any practical application of this logical ideal in the immediate future, and any adjustments of the wage system must be based upon the present methods of determining wages and the present general relations between the different occupations and industries.

The fabric of industry would not be able to withstand any severe change in its general methods of development. It can be improved only by the change in one detail after another, so that the machinery will continue to function through all the changes that must be made.

The investigation proposed by the American Federation of Labor will be affected by the practical necessities of the case. It is not likely that conclusions reached will depart materially from present practices, and for this reason any suggestions can be weighed more easily.

The practical ability of the labor leader to sense developments as they become visible is indicated again in this proposed investigation of wage systems. Manufacturers have been aware of the unsatisfactory character of wage adjustments and the necessity for better methods of determining wage scales. No investigations of importance have been made by professional organizations or manufacturers' associations.

It is evident that new considerations must be given to wage systems and methods of wage adjustment. These studies must take into account the elements affecting the efficiency of the individual worker and the extent to which they are related to the wage system. The elimination of the fluctuations in the efficiency of the indi-

vidual, the increase in the individual efficiency and the decrease in the waste must be measured in connection with any examination of wage systems looking to suggested changes.

It is unfortunate that professional societies and manufacturers' associations have done nothing along these lines, because investigations from this side will be necessary before any practical advance can be made in the wage systems themselves.

To be effective the reward should be based upon the service, it should satisfy the sense of justice, increase the incentive for improvement and develop confidence in the future. The reward must suggest safety in the permanence of the work and the removal of economic fear. Any moves that are made to change the wage systems in these directions will have a beneficial effect upon industry and upon the relations between management and labor.

It is interesting that the representatives of labor should have seen the necessity for this investigation before the representatives of capital and management have indicated their desire to improve things along this line, particularly as the examination of all factors is necessary to any just conclusions.

Industry would be well served if the leaders in professional and manufacturers' organizations, and the leaders of labor opinion could contribute their influence to an impartial investigation so that all the elements of inefficiency could be determined, the practical limitations in the systems examined and the possibilities of improvement considered.

The present investigation proposed by the American Federation of Labor will be limited by the traditions and precedents of that organization, and any of its conclusions will be discounted and discredited among manufacturers because of the source from which these conclusions come.

A great deal of progress could be made if the leaders in the professional and manufacturing groups would religiously study all suggestions for improvement, no matter where they came from, including particularly the investigations to be carried out under this resolution, by the executive council.

Despite the difficulties in the case and the probable limitations of the investigation, this proposed examination of the wage systems is likely to be the most important development from the present convention of the American Federation of Labor.

Classes of Research

PROF. LEONARD BAIRSTOW, speaking recently before the National Union of Scientific Workers, distinguished between scientific research, applied research, and experiments and tests. The three branches naturally merge into one another; yet Mr. Bairstow's main definitions will be accepted. Scientific research had, at the time it was carried out, no industrial bearing at all, he considered. A long period might elapse between the work of a Faraday or Maxwell and the stages of financial benefit. Scientific research needed an atmosphere of complete freedom from the anxieties of making both ends meet; the freedom implied communication of ideas with friends, unrestricted by national boundaries. Secrecy was extremely undesirable. Applied research had at the outset a definite industrial bearing owing to the difficulties of manufacturing processes. The work was allotted to research associations, to private laboratories and to Government departments; whether or not it should be secret was a controversial point. With certain safeguards the conduct of applied research could be materially helped by committees. The work, if worthy of the name, was slow and hazardous, and required co-ordination. By experiments and tests, Mr. Bairstow indicated the work necessary to meet a specific order after it had been placed. That work was of little general value, it was unsuitable for committees, and generally considered was confidential and urgent. For the routine tests of finished products, private institutions were better suited than highly-developed laboratories. Very special tests justified a certain number of central government laboratories empowered to issue certificates, but their range should be very carefully circumscribed. "If experiments and test work be carried out by a staff also allotted to applied research, the latter will suffer and tend to become extinct under existing systems of administration."

Speaking from his own experience, Professor Bairstow pointed out that applied research had difficulties in keeping alive in an establishment which used the same staff for experiments and tests. The latter were urgent, research was slow. The tendency was to push extra-experiment in ahead of research until the postponement of research was indefinitely prolonged. In order to keep research alive staff and apparatus should be specially provided for it. Further, the administrator responsible for finance had an additional temptation to favor tests which produced fees. A capable committee could here do much. If, however, the terms of reference of the committee covered both tests and research, the temptation to secure immediate results might prove too strong. That argument against intermingling applied research and experiments in the same establishment might also be made in the case of universities, though it carried less force there.

AN interesting opinion on motorcycle racing was expressed recently by the British journal, *The Motor Cycle*. Since it applies here, as well as abroad, the opinion is worth quoting:

"Does racing improve the breed? Undoubtedly; provided that the means by which races are won can be rendered applicable to touring machines without detriment to reliability or comfort. Such events as the Tourist Trophy and many of the long-distance races at Brooklands have done much to improve the cooling, reliability and general efficiency of the touring motorcycle; but what of the short-distance records? Let it be understood that we have no intention of disparaging the fine performances which have been accomplished over short distances. On the contrary, these phenomenal speeds are most interesting and instructive, and are productive of new ideals and new standards of performance. At the same time, it is evident that some of these records are of little immediate advantage to the average motorcyclist, since they are incapable of being sustained for any useful period. Provided the manufacturer of the record-breaking machine sets to work to incorporate the lessons he has learned in his touring mounts, well and good; but if he merely concentrates on obtaining an extra mile per hour on the track but little progress will be made."

Planning

IT sometimes seems as though manufacturers do not sufficiently recognize the importance of the old adage, "Be sure your right, then go ahead." Automotive manufacturers cannot be criticized for neglecting the latter part of the admonition, but expensive design changes, made after dies have been constructed, indicate that the "be-sure-you're-right" part is not always appreciated.

To draw a design, submit it to the parts maker, allow him to construct expensive dies and begin production is an expensive but legitimate part of manufacturing. To make frequent changes in that design after production has started is not fair either to the parts maker or the public. Such changes are sometimes rather arbitrary in character. They result in men being thrown out of employment, human hardships, production losses, increased costs and increased selling prices.

All of these things are to the detriment of industrial progress in general as well as to the manufacturer himself. Careful planning and a greater degree of co-operation by all men, companies and departments concerned will aid greatly in reducing or eliminating such unnecessary troubles and costs.

Heat Treatment Here Saves Trouble Hereafter

TWO cases have recently come to our notice in which failure to properly heat treat engine parts during the process of manufacture has lead to serious difficulty when the part has been placed in service with the result that articles possessing real merit have been blacklisted and will long be condemned as worthless, whereas a little intelligent forethought and care in development would have enabled the makers to benefit through recognition of intrinsic value of their product.

The first case is the aluminum piston. Many of the failures registered by pistons of this material were unquestionably due to failure to heat treat the piston prior to the final machining operation. As a result the pistons were put into service with casting strains unrelieved. Under the influence of heat in the engine the casting strains were relieved, the piston warped and much trouble resulted. To avoid this excessive clearances were sometimes allowed. Had the casting strains been relieved by heat treatment during the manufacture, the effect of distortion could have been canceled by later machining.

The second instance has to do with the tungsten steel valve. Some, at least, of the manufacturers who made these valves reasoned as follows: why bother to heat treat an exhaust valve when it is immediately subjected to high temperature when put in service? So many such valves were produced without heat treatment and placed in service. Forthwith they warped, for the internal strains had not been relieved and were quickly destroyed or rendered unfit for service until refaced. Obviously the warping should have been brought about by proper heat treatment before the final machining operation in production. Failure to do this has resulted in prejudice against the tungsten valve, though valves of this alloy possess considerable inherent merit and perform well in service when properly made.

Similar conditions apply in the manufacture of other parts subjected to heat or sometimes only to vibration during service, and should be borne in mind by the manufacturer if he desires satisfactory service from his product. Particulars of interest in this connection are given in the article by Dr. Rosenhain on Problems and Possibilities of the Aluminum Piston, which appeared in the recent Engineering Number of AUTOMOTIVE INDUSTRIES.

Recognizing Essential Factors

"WHEN employers have thoroughly defeated and broken the union organizations — if such a thing is possible—they will be far from a solution of the labor problem. The essential factors involved in human relationships lie much deeper and are much more complex than the mere battle between

employers' associations and union organizations." This is the opinion of a superintendent in charge of an open-shop plant employing more than one thousand men.

Similar opinions are being expressed by other far-seeing executives in various parts of the industry. The purpose of a labor policy is to get better quantity and quality production through the gaining of co-operation and enthusiastic work from the men. The purpose is not to win a victory or fight a battle to satisfy the employers' pride. In the long run it will be necessary to get the workers to go along with the management of their own free will. Hard times will not last forever, and the man whose only incentive is fear of unemployment is not the best workman at any time.

There is a certain manufacturers' association which meets every year and which devotes one session at each meeting to a discussion of the labor problem. These labor discussions are very private; no stenographic notes are taken, and the papers read are not published. The entire discussion at these sessions centers around the various methods of fighting the unions, the use of "scabs" during strikes, and many other practical defensive and offensive tactics of industrial warfare. To judge from the chief speakers' ideas, the millennium will have arrived when all unions and union leaders have been strung up to lampposts. When hard times frighten labor into temporary submission, a note of jubilation is sounded and progress is predicted. When times are good and labor comes into its own, there is weeping and wailing and gnashing of teeth.

The attitude and tenor of discussion of this manufacturers' association is still reflected too strongly in certain parts of industry. Permanent progress toward solving labor difficulties rests in a study of the individual, the various factors influencing his life and work, and achievement lies along the lines of careful study and thoughtful experimentation.

Needless Waste of Lubricants

A MARK of careless design or assembly is the pool of oil left on the garage floor or roadway by many cars even though they be new and presumably in good repair. A floor pan is required in many cases to prevent the floor of the show room from becoming stained, while our highways are black with oil dropped from cars and trucks which use them. A dollar a gallon is, one would think, a rather high price to pay for road oil, yet that is about what the average motorist pays for oil, a large proportion of which is ultimately deposited on the roadways wherever cars are used.

This would be bad enough, simply because it represents a waste which is in large part preventable, were lubricating oils cheap and the natural supply unlimited, but when the price of good oil is high and the supply decidedly limited the waste is not to be condoned, especially when there are many ways of minimizing if not eliminating the waste; such as thrower rings and flanges, felt washers, return threads, proper gaskets, better inclosure, with return ducts for oil, etc.

It is rightly considered a mark of poor design, construction or repair to see oil leaking from any machine in a well-kept shop or power plant. The mere fact that in the modern car the oil leak is hidden is no excuse for continuing a design known to be defective in this regard. This is a subject that may well receive more study on the part of the engineering, production and service departments of all producers of automotive equipment.

"Seek and Ye Shall Find"

HAVING once taken a certain side of an argument, it is a common human trait to maintain the justice of that side through thick and thin. Sometimes this takes the form of trying merely to prove that the other side is wrong. Frequently the desire to win the argument becomes so strong and the struggle of wits and resources so interesting that the actual purpose of the struggle is forgotten in the mix-up.

The relations between manufacturers and employees have arrived at this stage in many instances. Abuses on both sides have had the effect of emphasizing the struggle and obscuring its purpose. It is easy to point out the many faults of organized labor; it is easy to cite numerous individual instances in which the attitude and actions of the worker have been unfair. To do this merely proves that the way out suggested by organized labor is not feasible.

In reply to these criticisms, labor leaders oppose similar statements which show the unfairness of employers. Both sides have been rather successful in convincing their own groups. But the fundamental aim of each group seems to be to win the argument with the other.

Fundamentally, that is not the problem at all. The chief aim is to produce permanently harmonious industrial relations. This end can be achieved through seeking for truth, for basically correct facts, and for sound interpretation of those facts. So long as both sides seek and interpret facts with the idea of simply proving their side of the argument little progress can be made.

In his recent address to the S. A. E., President Beecroft quoted Rene Descartes, the French philosopher, as follows; the thought expressed applies equally well to the attitude necessary in considering industrial relationships:

". . . there is nothing so far removed from us as to be beyond our reach, or so hidden that we cannot discover it, provided only we abstain from accepting the false for the true and always preserve in our own thoughts the order necessary for the deduction of one truth from the other."

To realize this ideal fully in our mental processes may be impossible, but to approach the problem of human relationships with that thought in mind will make for practical progress; for more study and less propaganda; for more analysis and less argument. In this field, especially, we are still uncertain as regards the fundamental facts upon which to base extensive action. The time is ripe for a period of analysis and experimentation.

Banker Urges Price Stabilization

Big Market Waiting Final Adjustments

Gotham Bank President Says Makers Should Assure Present Price Values

NEW YORK, June 28—Henry H. Bizallion, president of the Gotham National Bank, which handles the accounts of more automobile dealers than all the other banks of New York combined, has written a letter to Alfred Reeves, general manager of the National Automobile Chamber of Commerce, suggesting that a marked advance could be made in the stabilization of the industry if car manufacturers would give assurances that present prices are excellent values and that no more changes are to be expected unless they are upward. He asserts that a survey made by the bank indicates that there is substantial purchasing power available for motor cars, but that buyers are waiting for the final adjustment of prices.

Reeves has asked members of the N. A. C. C. to comment on the suggestions made by Bizallion, whose letter follows:

"June 25, 1921.

"Dear Sir—As we handle more automobile merchants' accounts than all other banks in New York combined, we are deeply interested in the continued prosperity of the retail automobile business. This interest is very direct in that many of these dealers have been our customers for the past ten years.

Glad Adjustments Orderly

"Price adjustments in the automobile business, the same as in other lines of industry, were inevitable, and we are very glad to see that these adjustments came in much more orderly fashion than they did in other industries. According to your price lists all the readjustments seem to have been accomplished except for a few announcements that I understand will be made around July 1. The object of this letter is to learn whether you have any assurance from manufacturers that all price readjustments shall be made by July 1, so that the public will realize that the new prices are to continue over a substantial period.

"Would it not be well to suggest to all manufacturers that while no guarantee may be necessary, it would seem highly important to the prosperity of the retail trade that manufacturers endeavor to prove to the public that the present prices are excellent values, that in some cases they are made at a substantial but necessary loss during the readjustment period, and that for these reasons no further changes may be expected unless they are upward?

"During the past few years the banking fraternity has been led to look upon the automobile industry with the greatest respect, not alone because of its volume, but because of the energetic manner in which it has been conducted and our high appreciation that cars and trucks are now permanent necessities in our American life. Banks generally have been liberal with their credits to the industry, curtailment coming only in a few districts and in a few cases where the dealer was not entitled to credit, irrespective of the product he was selling.

No Loss on Dealer Business

"We take pride in the fact that in ten years of financing automobile dealers to the extent of many millions of dollars, we have never had a dollar's loss, except in one instance where fraud was committed.

"Our interest in the retail selling field has led us to make a survey, which shows:

"1. That there is a substantial purchasing power available for motor cars in particular, and to some degree for motor trucks, particularly in connection with new building operations that are now getting under way.

"2. Buyers generally are waiting for the final adjustment of motor car prices, to be assured that when they do buy the price will not change a few weeks later.

"3. It is the hope among dealers that all manufacturers who contemplate price adjustments will do so promptly and with the full understanding of the requirements of the next six or eight months.

"4. While guaranteeing prices may have many bad features, the makers should endeavor to impress the public with the new values in motor cars and

(*Continued on page* 1450)

British Car Makers in Market for Parts

LONDON, June 10 (By mail)—The Rover Co. of Coventry has established a precedent for British automobile makers by advertising in the newspapers for bids on practically all materials used in the manufacture of its 8 hp. light car. Hitherto the practice in the British automobile trade has been to invite a selected list of firms to bid. In some cases this does not insure competitive prices. The conditions require ability to quote close prices and guarantee delivery. There are intimations that American companies might find it to their advantage to compete for the reason that since the war British manufacturers have found themselves up against combinations in the castings and stampings trade.

Mexican Peace Big in Car Opportunity

Distributer Predicts Tripled Sales With Continuance of Present Normal Conditions

NEW YORK, June 27—The number of automobiles in Mexico to-day will be tripled or quadrupled within the next two or three years in the event that peaceful conditions continue throughout the Republic. This statement was made here to-day by F. G. Canton, the distributor in Mexico City of the Cole, Oakland and Cunningham cars and Brockway trucks.

The greatest drawback to increased use of automotive equipment in that country has been the danger in driving outside of Mexico City, Guadalajara, Tampico and a few of the other cities. Conditions have changed so materially in recent months, Canton stated, that this fear is being overcome and, when all parts of the Republic are again open for motor traffic, a great gain in the number of cars is expected because, as Canton added, Mexico has need of the transportation facilities offered by the automobile.

Road construction and highway improvement during the last six or seven months has been greater than during any similar period for many years. Practically all of the streets in the capital have been put in good repair and the highway activities outside of Mexico City have been large.

Canton is one of the backers of the new Association of Mexican Automobile Importers which was recently formed in Mexico City and numbers the principal firms engaged in automotive trade. The association has mapped out a big program for the next few years and it is expected that co-operative effort will enable the dealers of that city to overcome many of the present business difficulties.

WORCESTER BUYS STENMAN

WORCESTER, MASS., June 28—The Worcester Electric Tool Corp. has taken over the business formerly conducted by the Stenman Electric Valve Grinder Co., Inc., the Stenman Electric Tool Co. and the Consolidated Machine Tool Co., all of Worcester. The Worcester Electric Tool Corp., which was organized to take over the three concerns, is headed by H. P. Gleason. A. G. Sandberg is treasurer, J. J. Kelleher is sales manager and Harold Paine, advertising and service manager. The principal products which will be featured for the present is the Hus-kee service tools and drills.

Tractors Prove Superior to Horses

Fargo Farmers Get Impressive Lesson

Heat Forces Three Teams Out—One Machine Disabled—Attendance Small

FARGO, N. D., June 28—Forty tractor outfits and ten horse outfits started at 8 o'clock this morning in the first national tractor demonstration in this country in which a fair amount of work will be done by each. There is a ten-acre plot each tractor must plow and seed. It will take a tractor pulling three plows approximately ten hours to do the work and some with six plows expected to finish in half a day.

The ten-horse outfits were not entered by the Horse Association as tractor makers hoped would be done, but it was necessary for tractor makers to scurry around and get horse entries. Officials of the Horse Association refused to be drawn into a contest in which tractor makers drew up the rules without consulting with them.

The horse outfits belong to local farmers who, in most cases, are going to fare well, as some tractor makers are presenting them with machinery, such as plows, harrows and other tools used, in addition to approximately $1,000 cash prizes. It is questionable if any comparative results of horse and tractor efforts will be given the authority they should carry.

Only 26 different makes of tractors are competing, as compared with upwards of 70 makes at former demonstrations, the condition of the times being responsible for the reduced numbers. The most important makers are present except Samson and Moline. Among those competing are Fordson, Cletrac, Case, Wallis, Avery, International Harvester, Bates, Twin City, Emerson-Brantingham, Allis-Chalmers, Best, Deer, Huber, Gray, Hart-Parr, Aultman-Taylor. Holt, Rumely, Lauson, Nilson, Titan, Townsend, Rock Island, Fox, Liberty-Eagle and Grain Belt. The French cultivator, Souma, which takes the place of a plow will perform.

There is a growing feeling that the demonstration will not provide as good cost figures at it was hoped. The amount of fuel used and the time required will be obtained, but many of the factors entering into cost cannot be considered. Each tractor must be handled by one man, instead of a group of men, as at some former demonstrations, and the tractor operator must handle the plow without any outside help. Repairs on the tractor must be made by the operator. The ground to be plowed is dead level and is a black gumbo, covered knee high with weeds. Some trouble is expected in plowing it five inches deep, as required.

The very hot weather caused three of the horse outfits competing to withdraw before the first day was over.

The tractors competing gave a good performance, all starting at 8 a.m. and working on the hardest soil ever plowed in a national demonstration. Only one machine was disqualified for breakage. This was a Titan which had a defective driving gear that could not be repaired in the 30 minutes allowed for such work.

The three plow tractors finished their 10 acres in less than 10 hours and compared with the six horse team which pulled only two plows and did not plow half as much, they gave a good lesson to the farmers on the great economy in motor equipment.

The attendance was very small and even worse than last year. The novelty of the tractor has passed and whereas two years ago several hundred spectators followed the Fordson and other popular makes across the fields, scarcely half a dozen showed such interest today. Unless the attendance picks up in the last two days of the demonstration it scarcely can be regarded as a success, considering the cost.

Dakota farmers are not yet ready to buy. It will be July 20 before the status of the present crop is known definitely and farmers intend to wait.

N. A. C. C. Truck Survey Shows Farms Big Market

NEW YORK, June 28—The truck committee of the National Automobile Chamber of Commerce has completed its survey of motor trucks in use on farms in the states of Rhode Island, Maryland and Pennsylvania. The data shows that in Pennsylvania on 186,863 farms, only 12,631 trucks are in use and that there are only 11 counties in which there is no need for more trucks. Smaller sizes are preferred. In Maryland there are only 2817 farmers who use trucks. Most of them are of the 1-ton variety. It is evident that motor vehicles are popular in Rhode Island, because 1350 of them are in use on 3500 farms in Providence and Newport counties. It is stated that additional trucks are needed in Providence County.

DENY STINNES FIAT PURCHASE

NEW YORK, June 28—Reports from Turin, Italy, state that officials of the Fiat company deny that Hugo Stinnes, the German industrial magnate, has purchased a large block of Fiat stock. It is admitted that negotiations for the purchase of this stock were in progress, but are said to have been abandoned.

Congress to Impose High Aluminum Duty

Will Increase Tariff from Two to Five Cents Per Pound on Crude

WASHINGTON, June 27—It appears that the appeal of the National Automobile Chamber of Commerce to the House Committee on Ways and Means for low duties on aluminum products has been unavailing. It is stated in authoritative sources here that the permanent tariff, which the committee will report out by July 5, will carry a duty of 5 cents per pound on aluminum, aluminum scrap and alloys. The N. A. C. C. has asked that paragraph 143, under section 3, be left unchanged, or preferably, taken out entirely, as the present duty is 2 cents per pound. It was contended that the manufacturers of automobiles would use more aluminum if the price could be reduced by lower tariff rates.

Under the Payne-Aldrich Act, the duty on this material was 7 cents per pound, and in the Underwood-Simmons Act, 2 cents. Aluminum plates, sheets, bars, strips and rods were said to have been given a duty of 9 cents, as compared with 11 cents carried in the Payne-Aldrich Act and 3½ cents in the Underwood-Simmons law. The Ways and Means Committee was recently informed that the total production of aluminum in the United States is about 200,000,000 lb. per year, of which the automobile industry consumes approximately 100,000,000 lb., or 60 per cent.

It was charged that the Aluminum Co. of America owns and controls more than 90 per cent of the bauxites in the United States suitable for the manufacture of aluminum, and that it produces approximately 80 per cent and consumes about 90 per cent of all the aluminum in the United States. It was pointed out that if the duty is increased the foreign manufacturer will hardly be able to compete because of the additional custom charges when, with the margin at 2 cents, duty is already exceedingly small.

QUALITY TIRE MAKES OFFER

ANDERSON, IND., June 27—Stockholders of the Quality Tire & Rubber Co. have voted in favor of a proposal that the company issue bonds to the amount of $600,000 and that present stockholders take $100,000 of the issue. Creditors will be expected to take the remainder of the bonds to satisfy their claims and the subscription of the stockholders will be used as operating capital. The liabilities approximate $500,000.

Parts Business Slow Despite Car Sales

Heavy Retail Buying Not Yet Reflected in Orders from Manufacturers

NEW YORK, June 28—Notwithstanding the almost phenomenal sales of motor cars at retail in most sections of the country, the excellent trade of distributers has not been reflected fully in the business of parts and accessory makers. This would seem to indicate that numerous car manufacturers had on hand a considerable number of surplus cars when they suspended, in a large measure, the buying of materials late in May.

The business of parts makers is exceedingly spotty. Some of them are keeping fully abreast of their May business while others report there has been a sharp falling off in orders. Most of them have two or three motor car companies which are good customers, but are getting little business from others which previously have been on their books. It is probable, however, that the latter half of June will show a greater volume of business than the first half.

Reports from Detroit and other cities are to the effect that some parts plants which had contemplated a shutdown at the beginning of July, ostensibly for inventory purposes, will continue operations through the month, although on a reduced scale. Many of the car makers have found it necessary to increase their schedules to meet the demand for cars resulting from increased sales due to price reductions and this ultimately will reach back to the men who supply them.

It is certain that the slowing up of the industry in July will not be so marked as was expected a month ago. Underlying conditions are thoroughly sound and there is reason to believe that after the middle of September there will be a steady upward trend.

Credit conditions, especially in the smaller cities, are not entirely satisfactory. While the banks have more cash available than for many months, they are loaning it with the utmost caution and many manufacturers are having considerable difficulty in obtaining funds with which to finance the orders they are receiving. There is a tendency on the part of many bankers to send their surplus funds to New York.

Parts makers generally, however, report collections for June better than for any month this year. There has been a continued whittling down of past-due accounts.

New Orders to Keep Timken Plant Operating

DETROIT, June 29—Decision to close the Timken Detroit factory for a month July 1 has been altered as the result of orders coming in steadily, which will necessitate operation of the plant on the present basis of 1/3 normal for the next 60 days at least, according to General Manager Fred Glover. Orders are coming through every day, said Glover, and though in small volume are sufficient to keep the factory working.

The same is true of Continental Motors, which, although no definite closing date had been fixed, had anticipated a slowing up around July 1 with a possible temporary shut down. Vice-President G. W. Yeoman said the plant would continue to operate on the present basis and all indications point to a steady demand. Yeoman reiterated his statement that the company would operate just as long as compelled to by incoming orders and from time to time might shut down for two or three day periods, though no general closing down was anticipated.

Hupp Favors Short Closings

The same attitude is apparent at the Hupp Motor Car Corp. plant. Hupp has been building 80 cars a day, basing production strictly upon sales demand and it is the intention of Hupp executives to close down for short periods from time to time as the market fluctuates. President Hastings said demand is brisk and there is no indication to-day that the plant will have to slow up.

Employment figures for the last week in 79 factories in Detroit show 559 less men at work than during the week previous. The total employed was 109,621 in the 79 factories which includes practically all the automobile plants. Short time schedules were in force in 25 concerns which were working 6391 men on an average of 21¼ hours weekly. The figures are for the week of June 21.

Upstate concerns appear to be in good shape as far as production is concerned, due to the stimulation in sales as a result of the price cuts. This is true particularly of the Wilson Foundry & Machine Co. at Pontiac. Orders bringing production close to the maximum of last year are reported by D. R. Wilson, general manager.

"We passed the 1000 mark on the payroll last week," said Wilson, "and we are so busy trying to keep up to the demands of the Overland plant that we expect to be compelled to work a Sunday shift. Rush of business at the Willys-Overland plant is keeping up, and reserve orders have grown to such an extent the plant is assured of its schedule through August.

"We have orders to turn out 550 jobs a day and that number is going through the shop. The Overland plant, however, will use that number, so we have little chance of getting ahead of it. This will necessitate our working on Sunday. We have been summoning former employees wherever it was possible to locate them, and the total number on the payroll has been substantially increased within the last two weeks."

FISK ADDS NIGHT SHIFT

CHICOPEE FALLS, MASS., June 27—The Fisk Rubber Co. has added a night shift of 300 men to its force and has increased the day force by 250. Increased demand for certain sizes of tires is the reason for the expansion of production.

Milwaukee Plants to Resume July 1

Accumulation of Finished Stocks in Factories Now Sold—Expect Steady Demand

MILWAUKEE, June 27—Between July 1 and 5 there will be a general revival in the operation of passenger car factories in this and other centers of production, while at the same time some shops which have been virtually closed down for a number of weeks will resume work. The recent accumulation of finished stocks has been worked down to the point where new production is necessary and new orders from distributors and dealers are being received in a relatively generous measure.

The trade has received material assistance in moving goods by the recent price reductions and this good influence is being passed on to the factories. Makers of parts and accessories and general equipment are proceeding at a fair rate of output and expect to be in position to make steady progress. In general, the opinion is expressed that with the resumption after July 1, factories will be able to run steadily until the end of the year at least.

Business and Financial Comment, a monthly review of local industrial and commercial conditions, issued by the First Wisconsin National, the largest bank in Milwaukee, says the following concerning the automotive industries:

"With one or two exceptions, business in automotive parts and accessories fell off in May compared with April. Gratifying as the gain in this line has been during the spring months, the business done falls 40 or 50 per cent short of the same months last year. The recent and rather abrupt decline in motor car sales is to a considerable extent seasonal.

"The experience of the spring season, however, has shown the industry that cars were priced too high for the buying power of the country. The letting down in prices of most of the leading companies may bring out a better demand in the fall selling season, especially if general business revives.

"The tendency of prices in automotive lines, to a large extent, hinges upon stabilization in the steel industry. Demand for motor trucks parallels new construction work. Demand from that source this year so far has been limited, as the carry over of trucks from last year is nearly sufficient to take care of needs until new construction of all kinds expands."

DODGE LINES UP WITH N. A. D. A.

ST. LOUIS, June 28—Following the action of Charles W. Matheson, sales manager of Dodge Bros., in recommending that all Dodge dealers become affiliated with the National Automobile Dealers' Association, General Manager Harry Moock announces that there are now 297 Dodge dealers enrolled.

Durant Sold Ahead on Eastern Output

Orders for 20,000 Schedule at Long Island Plant Placed—Car Details Given

NEW YORK, June 28—Production of the new Durant car will be started at the Long Island City plant about Aug. 1. It is understood that approximately 20,000 orders for the car already have been received from the Eastern territory. This will keep the plant running at full capacity for a year. Experimental work on the four-cylinder car, which will sell for $890, has been completed and it is practically ready for inspection.

One of the main advantages of the car, its makers contend, is the low maintenance cost which will result from the remarkable accessibility of its various parts. Another point in its favor is said to be the unusual number of refinements in body design. More than the usual amount of leg room is provided in the front seats and the same is true in the rear. The car, which will weigh 2300 lb., fully equipped, will be rated at 24 hp. and will develop a speed of 50 m.p.h. on a level road. Tests have demonstrated that it will average 17 miles per gallon of gasoline.

One of the principal features of the chassis construction is the use of two tubular struts between the cross frame members. These are used not only to stiffen the frame and take out a good deal of the weave, but are also used in place of the exhaust pipe and muffler. These simply act as an expansion chamber and there are no baffle plates used in the construction.

Special Continental Engine

The engine is a four-cylinder block type, made by Continental especially for the Durant car. The valves are of the overhead type, are inclosed, and the exterior of the engine is very smooth and clean. Ignition is by a battery system and the coil is mounted on top of the timing gear case. Servicing has been very carefully considered and all the members, including engine, clutch and gearbox, can be removed without disturbing any of the other members. The oil pump is of the rotary type, very small, and is on the outside of the crankcase at the right, with the water pump on the left side. Aside from these, and the coil, there is practically nothing on the outside of the engine.

The clutch is of the plate type, with a single steel disk, which is slotted, to allow for expansion under heat and prevent warping of the plate. The plate has a molded asbestos floating ring on each side, and the entire assembly is taken out by taking the cap screws out of the cover plate, which carries also the expanding fingers.

The instruments are mounted on a sheet steel instrument board, painted, varnished and grained to represent Circassian walnut to correspond with the rest of the woodwork. The steering wheel is solid walnut and the spider is partly aluminum and partly walnut, giving a very handsome appearance. Upholstery is in real leather.

The axles are fitted with Timken bearings, and the rear is of the three-quarter floating type. The carburetor is a Tillotson. Springs are semi-elliptic and the extra tire carrier on the rear is so mounted as to make a very stiff job. The tires are 31 x 4 and are on artillery wood wheels.

The body appointments are very well looked after and there are pockets in each door, each one accommodating the curtain which goes directly above it. The rear deck is double, with the straps concealed between the plate glass rear window.

TWO NATIONAL SHOWS ARE SET FOR JANUARY

NEW YORK, June 27—Dates for the 1922 New York automobile show have been tentatively fixed for Jan. 7 to 13. The show will be held in Madison Square Garden. The Chicago show will open in the Coliseum Jan. 28.

Warner to Reincorporate as Delaware Corporation

TOLEDO, June 27—Preliminary notice of the dissolution of the T. W. Warner Co. of Muncie, Ind., has been filed at Indianapolis preparatory to turning over the assets of the Indiana company to a new corporation of the same name which will be incorporated under the laws of Delaware. Explaining the plan to-day, T. W. Warner said:

"Our business has been enlarged to such an extent that new corporate powers were needed. We will be affiliated with Durant Motors, Inc., but will not become a corporate part of it for some time at least. Manufacture of parts for the new Durant car is going forward and production is increasing from week to week."

DURANT IN NEW QUARTERS

NEW YORK, June 28—W. C. Durant and the headquarters organization of Durant Motors, Inc., is now settled in its permanent location on the eleventh floor of the new Gotham National Bank Building at Broadway and Fifty-ninth Street. Admirers of Durant signalized the move by sending him quantities of flowers, which greeted him when he reached his office Monday morning.

GERMAIN DENIES REPORT

DETROIT, June 28—Leon R. Germain, vice-president of the Old Motor Works, denies that he will resign to join Edward Ver Linden, former president of Olds, in the development of the Durant Motors of Michigan, in Lansing.

Overland to Make 12,000 Cars in July

Sales for Month to June 15 Reported 18,000—Other Toledo Plants Busy

TOLEDO, June 27—The automotive business increase which has forced the enlargement of working forces at the Electric Auto-Lite Corp., the Champion Spark Plug Co., and has necessitated the working of a night force at the plant of the Mountain Varnish Co., was emphasized when Willys-Overland officials gave out the word that the July production schedule was for 12,000 cars as a minimum.

If production can be speeded up as the month rolls along it will top this number by several hundred. And then orders will not be met. In June the Overland has gone far in building up its organization. Production of cars for the month was fully 100 per cent above the number turned out for May.

Sales Manager A. C. Barber announced this week that the Overland sales from May 16 to June 15 had amounted to 18,000 cars. Actual delivery in the first two weeks of June exceeded 6500 cars, according to his report.

For the first time in months the Willys-Overland Co. is advertising for all kinds of mechanics. They are being absorbed into the forces at the plant here at the rate of about 200 a day. A drive-away of 150 cars on Friday illustrated the way things are going. Of these cars 35 went to Columbus and 25 to Cincinnati and the rest to intermediate and smaller towns.

The Mountain Varnish Co. is practically a subsidiary of the Overland. The calls for paint and varnish for the automotive trade has forced the plant to get into top speed production this week.

The Auto-Lite factory here has been crowded with work for more than a month and it is noticing a gradual increase every week.

Overland Price Change Creates Business Rush

PHILADELPHIA, June 25—Passenger cars are being shipped by factory to Philadelphia in large numbers, which promises well for the industry.

For instance, the Overland-Harper Co., according to H. B. Harper, president, is enjoying an increase of more than 40 per cent over the business done for this period in 1920 and a 70 per cent increase over that done in the corresponding period of 1919. Since the price reduction, Harper says, orders are coming in so fast that they cannot be filled. A solid trainload of Overlands and Willys-Knights has arrived.

"The first eight days' business in June is the greatest for the period that I have ever had," said Harper.

Ninety per cent of the cars on the way, added Harper, are promised.

June Sure to Lead Year's Sales to Date

New York District Far Behind on Deliveries—Summer Outlook Improved

NEW YORK, June 27 — This month unquestionably will be the biggest month of the year to date in passenger car sales in the metropolitan area. Cars on which recent substantial reductions were made are selling heavily and others whose reductions were announced in May, have not yet lost entirely the impetus given by lower prices. Business as the month closes indicates that the July and August let-down in sales will not be any more serious proportionately than it has been in past years. Practically all dealers expect sales to drop off materially during those two months, but that is a perfectly natural condition in any community which is intensified in New York by the fact that a large percentage of the people who own or are able to own automobiles spend the heated months out of town.

Buick, Studebaker and Dodge, whose salesrooms have been flooded with orders since their recent reductions were announced, are still considerably behind on deliveries and some of their disappointed customers are turning to other makes of cars, which is helping business generally. Maxwell ran behind on deliveries in May but has been able to catch up this month.

In Brooklyn, where some of the motor car establishments rival those of New York proper in importance, sales have been heavy throughout the month. Dealers there are also having a fairly lively service and accessory business.

The Bronx and Westchester Counties and Newark, N. J., also report big sales.

Richmond County, which comprises Staten Island, lying in New York harbor, has had a fine May and June business in practically all lines. Buick, Overland and Ford dealers are oversold and are forced to ask customers to wait.

Motor truck business in the metropolitan area, which was not as good in May as it was in April, is picking up again.

The used car business has been seriously affected by repeated reductions in new car prices and the public is showing a hold-off attitude. A fair number of sales are being made but in many cases these are at a sacrifice, owing to sudden new car reductions depreciating values of used cars in dealers' hands.

FAR WEST OUTLOOK BETTER

RACINE, WIS., June 27—John Tainsh, general sales manager of the Mitchell Motors Co., Racine, Wis., has returned from a tour of investigation of business conditions and prospects along the Pacific Coast. Concerning his findings he said: "Things look decidedly better in the Far West and Pacific slope and I feel sure that within a few weeks the whole automotive industry will be in much better shape. My swing out to the Pacific has shown me that already buying has become much better and that the interest in motor cars, the growing tendency to regard the automobile as an essential part of our economic structure is just as great."

Bank President Urges Quick Price Action

(*Continued from page* 1446)

to show that the industry has now been stabilized after these midseason price changes, that no more changes are probable, and moreover, that if there should be any further price changes it would more than be offset by the reduced value of the car which the average buyer now has to trade.

"From our survey of the field it would appear that the new prices represent extraordinary values in motor cars, because they are so little above the pre-war prices, to say nothing of the fact that many of these new models are better equipped, better made and better finished than the products of five years ago.

"While I appreciate the difficulty of concerted action by nearly two hundred manufacturers of motor cars and motor trucks in an industry as big as yours, the National Automobile Chamber of Commerce has been such a constructive force for so many years and the automobile industry is in so much better shape than the majority of trades in this country, that I hope your organization will undertake to convey to its members some of those things which I am prompted to suggest because of our high interest in the motor car sales in the eastern territory.

"Can you, or through you, can the manufacturers, give us any assurance of a continuation of operations by the manufacturers on the present basis of prices and values? Some certainty along these lines will materially help the dealer in his plans for maintaining his organization and sales work that would permit broader plans for financing his requirements on the part of banks and ultimately be for the best interest of the public, the manufacturer and the retailer.

"Please be assured of the readiness of our bank to render every possible assistance in the solution of this problem for further stabilization of the automobile industry."

FORT WAYNE BUSINESS GOOD

FORT WAYNE, IND., June 27—While the automobile business in this city is not as good as it was a year ago, the leading dealers seem to be pretty well satisfied with the business they are doing under present conditions.

S. F. Bowser & Co., pump manufacturers, have put on a night shift of seventy men and the Wayne Oil Tank & Pump Co. has been working overtime for some time. The Dudlo company, manufacturer of magnet wire, is also showing a good increase.

Fall Outlook Cheers Cleveland Dealers

Feeling Unanimous for Profitable Business—Buying Starts in Rural Communities

CLEVELAND, June 28—Cleveland retail automobile dealers are a unit in saying that the business so far in June is better than it was in May. A great many of the dealers visited said that the record for June this year is better than it was a year ago. Others made the statement that deliveries of cars for the first six months of this year are greater than a year ago in the same period, and their net profits are running higher this month than in June, 1921.

The big point about the Cleveland retail dealer is that he is cocky about his prospects for the next six months. Every man along Euclid Avenue is dead certain that he is going to enjoy better business the next six months than he did a year ago; in fact he expects to go way ahead of the figures for the last half in 1920.

Wholesale dealers have been cheered by an increased demand by Ohio farmers for cars. They are buying better than they did earlier in the year. The crops are soon to be harvested and that is said to have an influence on the market. Dealers in small towns throughout the Buckeye State are coming here more frequently for cars this month than they did in May or in June a year ago. Long strings of new cars that are being driven away may be seen daily on the streets.

WESTERN SUPPLY ADDS STORES

SEATTLE, June 27 — The Western Auto Supply Co., operating a large chain of automobile tire and accessory stores in the western half of the United States and capitalized at $3,000,000, has just completed negotiations for the purchase of the eight large stores owned and operated by the Autoparts Supply Co., a half-million-dollar corporation, operating in Seattle, Portland, Tacoma, Spokane, Yakima, Bellingham, Walla Walla and Boise.

For the present the stores of the Autoparts Supply Co. will be operated as a subsidiary company, and there will be no radical change in management or personnel.

PREMIER SEES CLOSED DEMAND

INDIANAPOLIS, June 27—H. E. Doty, sales manager of the Premier Motor Corp., believes closed body jobs will increase during the present year and will be in greater demand next year than ever in the history of the industry. Because of this belief, production schedules at the plant have been changed so that now about 40 per cent of the cars produced are closed cars. According to Doty, orders during the past month or six weeks indicate a decided change to this type of body

Plenty of Business Reported in Kansas

Principally Matter of Salesmanship—Price Cuts Encourage Dealers—Harvest Near

TOPEKA, KAN., June 25—Business in Kansas in largely a matter of what the dealers make it. Live dealers everywhere are selling cars, and this does not mean necessarily dealers in cars whose prices have been slashed in the present reductions. There appears to be business where it is properly gone after, even in the oil producing section of the State, which is now in considerable of a slump due to low crude prices.

General business in the northern part of Kansas is in better condition than in the southern oil territory. Whatever sales resistance there is in this section is being dispelled by the live dealers. There are some complaining of lack of business and a few who speak of cutting into some other line after July 1, but most dealers are keeping busy.

Wheat is in good shape in practically all sections of the State, but there will be no definite reactions based on the crop until after the harvest which starts now at any time. Business in Kansas is bound to be better after the harvest. It always was before and it will be now.

Price reductions seem to have had a greatly beneficial effect in all towns. Dealers are going after business greatly fortified by the price argument and are closing sales which were impossible under the old prices. Many buyers were known to be merely waiting for the reductions and their closing was a mere matter of form. One dealer whose weekly sale average was two sold fourteen in the first week after his car was cut.

The morale of dealers as a whole is good. There has been some discouragement from various causes during the past few months, but they have been holding on well and are now regaining their former pep.

REPORT MORE SALES FOR CASH

QUINCY, ILL., June 25—Automobile trade is fast returning to conditions of two years ago, according to R. H. Patterson, local Overland dealer, who adds that there has been "more business in the last two weeks than in the last two years."

Recognition that the automobile trade has hit rock bottom in prices, he believes, has encouraged buying and purchasers come into the market with more free money, less chattle mortgages and promissory notes than in late months.

PRICES HURRY PURCHASERS

FORT WAYNE, IND., June 25—The recent price reductions in some of the leading makes of cars brought a veritable rush of orders and to the local dealers handling these cars. The Shryock Automobile Co. sold nine Buicks on the first day after the price reduction went into effect to purchasers who came to the company's salesroom without solicitation. The Hayner Co., dealers in Ford, reports that the Ford reduction quickened business immensely. It is expected that the present boom in the selling of cars in this city will continue for some weeks at least. Dealers believe that a great many local people who have really been wanting cars have been holding off buying on the hunch that the price reductions were sure to come.

Grain Harvest Brightens Trade Outlook in Texas

DALLAS, TEXAS, June 27—The automotive industry in Dallas and this district continued to show an improvement generally during the first half of June. There was not a line of the business but reported improved conditions and brighter outlook. The prediction is being made freely in Dallas that the industry in Texas will be back to normal before the snow flies.

Dealers reported more cars sold during the first fifteen days of June than any other month of the year. This was even true of the used car dealers. An important point is the dealers are selling for cash. Truck dealers reported increased sales and deliveries.

Tire men declare business looks like old times.

There has also been an increase in the business of the implement and tractor dealers. This probably was due to harvest time or necessities for new farm machinery. In these lines prospects are much brighter. In some instances it was said grain farmers are now paying accounts more than a year old. The implement and tractor dealers believe with a $40,000,000 grain crop being harvested in Texas their business as well as that of the motor industry generally will be much better during the remainder of the year.

Approximately $100,000,000 worth of roads are under construction or will be before the year is gone.

NASH REOPENS "FOUR" DIVISION

MILWAUKEE, June 27—The four cylinder car division of the Nash Motors Co. at Milwaukee, which was virtually shut down June 1 pending readjustment of materials and stocks, will reopen July 5 at the same capacity. About 850 men are being called back to work. The Milwaukee plant is under the general management of B. W. Twyman.

DETROIT BODY PLANT SOLD

DETROIT, June 28—Hugh O'Connor, president of the Michigan Wire Cloth Co., was high bidder for the property of the Detroit Weatherproof Body Co. sold by the Security Trust Co. as receiver under an order of the Federal court. O'Connor bid $140,000 for the property as a going concern and his offer will be submitted to Judge Tuttle for acceptance or rejection.

California to Keep Sales at High Point

Dealers Turn Down Proposals for Week End Closing—Registrations Heavy

LOS ANGELES, June 25—During the four months beginning Feb. 1, California has been buying automobiles at a heavy increase over the corresponding period of 1920. Feb. 1 is picked because that date starts the registration year in this State. Fees exceeding $6,000,000 have been collected by the motor vehicle department in that period. These have been paid by 540,000 automobiles, 30,757 trucks, 2,456 trailers and 14,427 motorcycles. The increase in fees over the first four months of 1920 has been $1,150,000. Motorcycles show a reduction in numbers and a corresponding loss in fees.

In Southern California during May, 4888 new passenger cars and 632 new trucks were registered, a total of 5520. The gain in passenger cars over April was 727. The total registration from Jan. 1 to June 1 in this part of the State was 21,125, which includes a gain of 2274 passenger cars over May, 1920. A very interesting fact revealed by the registrations is that more higher price trucks have sold than passenger cars of an equal number of makes and corresponding prices. The leading passenger car gains made in May over April were: Buick 50, Ford 246, Chevrolet 133, Hupmobile 51, Oakland 69.

Comparatively few price cuts had been put into effect during May and the brisk business is to be attributed more to hard work on the part of dealers than anything else. The buying public has not been allowed to become pessimistic and lose sight of the need for motor vehicles. With price cuts to help out, it is predicted that June will be a record breaking month.

That the dealers propose to keep on working at top speed was demonstrated at the meeting of the association to-day, when it was voted against Saturday afternoon closing. Some salesrooms are remaining open at night and a few have gone so far as to advertise they are open Sundays, too. The latter has not become a general practice but there is no foretelling what the precedent may bring about.

TEXAS TAKES BUICK TRAINLOAD

DETROIT, June 25—Col. B. B. Webb, Buick branch manager at San Antonio, Texas, left an order this week at the factory in Flint for a train load of Buicks. Col. Webb declares automobile sales in Texas are picking up rapidly and the section is fast recovering from the slump which appeared to be more acute there than any other place in the country. George S. Schroeder, general manager of the Vesper-Buick Co. at St. Louis, also was at the plant this week arranging for a 400 car shipment to the dealers in his territory.

Big Nitrate Plant May Go to Ford

Visit to Muscle Shoals Admitted at Offices as View to Purchase —Power Facilities Large

DETROIT, June 28—Henry Ford has inspected the immense Government nitrate plant at Muscle Shoals with a view to buying the property. This was admitted at his offices to-day, but all further information was refused. There has been no intimation as to what disposition would be made of the plant if he acquired it. Completion of the great Wilson dam and carrying to a conclusion of the original plans of the Government for the production of nitrate, would provide enormous quantities of nitrate for fertilizer and would be a great boon to the farmers of the United States.

Favorable Steel Supply

BIRMINGHAM, ALA., June 28—Henry Ford recently went to Muscle Shoals incognito and examined the Government property. He was discovered just about the time he was ready to leave, but refused to give out any information, simply saying that he was inspecting the Government property.

Aside from the advantages to be gained in operating an automobile manufacturing plant at Muscle Shoals, the two nitrate plants, now completed, furnish a splendid opportunity for money making and service. The plants, with slight alterations, will manufacture fertilizer, leaving them intact for the manufacture of nitrate for gunpowder in case of another war.

The power house, which is already complete, is the second largest in the world, engineers estimating that the Government spent millions in making it modern in every way.

Many advantages would be realized by the purchaser of Muscle Shoals, especially if he happened to be an automobile manufacturer. Freight rates, both by water and rail, are lower than at other inland points. Sheffield and Florence have three furnaces from which materials for steel can be had, eliminating the necessity of hauling iron from some distant point.

The Tennessee River is a larger stream than some of the principal waterways of the country, and but for the obstacle of Muscle Shoals would be navigable from Knoxville, Tenn., to the Mississippi River.

Muscle Shoals offers an ideal site for a hydro-electric plant. It is 18 miles in length and has a fall of approximately 100 feet. By damming the river at the end of the shoals immense power would be developed, and at the same time the dam would open the river to navigation for its entire length. Wilson dam, as planned, is a gravity section structure about four miles east of Sheffield and two and one-half miles from Florence.

The dam crest is 80 feet above the elevation of the river bed, carrying gates 18 feet high and raising the water level to a height of 98 feet above the stream bed. This creates an available maximum of 500,000 hp. Four units of 30,000 hp. each have been contracted for, and space for 14 additional units have been provided for in the power house design, each carrying 30,000 hp.

Experiments on products which heretofore came from Germany could, if the property was purchased by a manufacturer, be continued as nitrate plant number 1, which was built for experimental purposes and which has been used for testing and making dyes and other experimental work.

Central Products Group to Double Work Force

DETROIT, June 27—Central Products Division of General Motors Corp. contemplates doubling its working force in Detroit within the next 30 days. From 2000 to 2500 men are employed at present by that unit and this number will be increased to at least 4000 in the next month. Within five months the new plant of the Central Products Co. will be completed and the working force increased to about 6000.

The information was disclosed in a request of the corporation made to the City Council Saturday in a petition asking for the widening of Holbrook Avenue from St. Aubin Avenue to the Grand Trunk Railroad. The petition asked that the street be widened to 86 feet and paved with asphalt. the corporation offering to give a strip 10 feet wide on each side, but asked that it be relieved from any special assessment and that the city replace the present sidewalk.

The Central Products Division includes the three factories located along the section which the corporation seeks to have widened, and are the Central Axle Co., the Central Gear Co., and the Central Storage Co. The new factory in process of construction is the Central Motor Co., also a part of General Motors.

The petition to the council was signed by L. B. Robertson, general attorney for General Motors Corp. The petition states further that at the end of 10 months it will be necessary to put on night shifts, increasing the corporation's working force in the Central Products Division to 9000.

R. & V. OPENS FACTORY BRANCH

EAST MOLINE, ILL., June 27—R. & V. Motor Co. has opened a factory sales and service branch at Cincinnati, operated by a corporation separate and distinct from the manufacturing company, but controlled by the same interests. It will be known as the R. & V. Motors of Cincinnati, Inc. Paul Andree, who has been associated with the company for twenty years, has been appointed manager. and will be in charge of the retail and service division. Formal opening will be Aug. 1.

Denby Creditors Act on Company's Future

Meeting to Decide on Receivership or Continued Operation Held in Detroit

DETROIT, June 29—The future of the Denby Truck Co. will be decided at a meeting to-morrow afternoon of the 55 creditors whose claims remain unsatisfied. While no definite plan has been outlined, it is the belief of the creditors committee that continued operation, even under the present market conditions, would be better than liquidation, which it is declared would be suicidal.

Application for a receiver, in the opinion of E. R. Ailes, treasurer of the Detroit Steel Products Co. and a member of the committee, could mean only liquidation, for it is considered highly improbable that a court would authorize continuance of business under market conditions now prevailing.

"We have not had a meeting for six months," Ailes said, "and we want the creditors to get together to talk over the situation and decide upon the best move to make. We want them to say whether the plant shall continue in the hope of better times or liquidate the property.

"All but 55 of the creditors have been paid off by Major Edwin Denby and J. Walter Drake, but of course their claim stands against the company. The total indebtedness, including banks, approximates $650,000. There are no bonds outstanding, however, and the plant is free and clear. The only need now is working capital, but no one can be found at this time in a position to advance the money needed.

"We have abandoned the idea of refinancing at present. We could, of course, raise money by means of a stock issue, but that is out of the question, particularly at this time with Major Denby in the Cabinet. My idea is that it is better to keep going and turning over as much as possible, losing a little each month. but that is up to the creditors to decide. The company is no worse off than others which are operating at a continued loss.

"Creditors who attended the last meeting were highly satisfied. Naturally there are disgruntled creditors, one of whom started suit, but we satisfied him, and I am inclined to believe it will be decided to continue operations. The company has a splendid plant, a good product and an opportunity to make money when business conditions improve.

TIMKEN BEARING ADDS MEN

COLUMBUS, June 27—C. N. Repogle, general manager of the Columbus branch of the Timken Roller Bearing Co., has increased the force at the plant from 250 to 450 men. He is of the opinion that still further additions to the working force will be necessary.

Offers Resolution to Bar Trucks

Graham Asks Tax to End Reimports

Proposes 300 Per Cent Duty on All Supplies Sold Abroad by Government

WASHINGTON, June 29 — Congressman Graham of Illinois, formerly chairman of the select committee of the House to investigate expenditures in the War Department, has introduced a joint resolution which would specifically prohibit the reimportation of surplus war supplies except at a duty of 300 per cent, which in effect would be an embargo.

In a statement to AUTOMOTIVE INDUSTRIES to-day, Graham stated that the resolution covered all supplies sold abroad by the Government and was drafted in order to expedite legislative action. He expects its passage in the Senate and House before the tariff bill has completed the circuit.

The permanent tariff bill, as reported out by the Ways and Means Committee to-day, contained no specific reference to reimportation of trucks as had been anticipated in some quarters. It is possible that this situation may be remedied on the floor of the House during the tariff debate when the bill is subject to amendments.

Congressman Graham stated that he was convinced his resolution would prove more effective. Assurances have been given, he said, that the Ways and Means Committee would approve it as a special measure looking toward the protection of domestic markets.

The joint resolution fixes a duty of 300 per cent ad valorem on all goods, wares, merchandise, military and naval supplies of any kind whatsoever originally exported from the United States for use of the American Expeditionary Forces or their Allies, when reimported into this country. Graham is acquainted with the practices of European and American speculators in buying this equipment at extremely low prices, generally below cost, and reselling in this country after slight alterations or remanufacture. The flat rate will apply at American valuations.

Provides Retaliatory Motor Vehicle Duty

WASHINGTON, June 29 — Retaliatory duties against countries which erect tariff barriers to stop importations of American automobiles has been provided in the permanent tariff as reported by the House to-day by the Committee on Ways and Means after six months' study.

The bill proposes a 25 per cent ad valorem duty on imports of automobiles, automobile bodies, automobile chassis and parts of automobiles including tires. Special provision has been made for the establishment of reciprocal relations under the direction of the President, a plan approved by the National Automobile Chamber of Commerce.

The rates on automobiles are 59 per cent lower than the N. A. C. C. had recommended but sufficiently high to prevent effective competition from foreign manufacturers. The duties had been 45 per cent on higher priced cars and 30 per cent on medium priced machines.

The retaliatory measure is not confined to automobiles, but it is aimed at the French and Italians who put up tariff barriers last summer with specific rates for motor cars. It is provided in that if there be imported into the United States any of the articles manufactured in or exported from any country which imposes a duty greater than 30 per cent ad valorem upon similar articles exported from the United States, there shall be levied on such articles a duty equal to the duty imposed by such country upon such articles imported from the United States, but not to exceed in any case 50 per cent ad valorem.

A rate of 30 per cent is applied to imports of aircraft as a retaliatory duty.

Dowell Road Bill Is Passed by House

WASHINGTON, June 29—Highway legislation has struck a snag here owing to the passage of the Phipps-Dowell bill in the House this week, providing for continuation of the Federal aid system with a system of interstate roads and a commission to direct the work.

The Senate has this bill and the Townsend bill pending. It is a question of parliamentary tactics which shall have the right of way in the Senate. It is believed that Senator Townsend will effectively block the Dowell bill in the Senate unless the essential principles of his measure, endorsed by the National Automobile Chamber of Commerce and other automotive organizations are accepted in amendments.

Truck Auction Bids Appear Fictitious

NEW YORK CITY, June 29—Auction of 200 reconditioned army trucks reimported into this country by the Truck Co. of America was started here to-day and will continue until July 1. Judging from to-day's sales there was very little participation in the bidding by the public and the sales prices were seemingly fictitious. Macks of 5½-ton capacity sold

(*Continued on page* 1459)

Congress Clears Way to Action on Trucks

May Include Protective Principle in Anti-Dumping Provisions of Tariff

WASHINGTON, June 27—Indications are that the House Committee on Ways and Means will dispose of the reimportation evil, which has affected automobile dealers more than anyone, by a special clause in the permanent tariff bill as a principle of protection rather than a specific class legislative measure. Incorporated in the anti-dumping provision, it would become one practicable and available method of checking the re-sale of American trucks in this country by foreign sales agencies which purchased them as surplus army equipment. The Class Journal correspondent was advised by high official sources that diplomatic efforts to adjust the situation had failed and it became solely a legislative matter.

It was learned that this government had made representations to the Government of France but was subsequently advised that the French authorities were powerless to prevent reshipment of American trucks and other goods. The correspondent was informed that the admission into or exclusion from the United States of these products is not covered by contract or treaty stipulations under the administration of the State Department. It is not accurate to imply that the State Department objects or has objected to efforts looking toward restriction of sales of trucks or other army supplies.

Dealer Action Unopposed

In other words, the State Department has entered no objection to the campaign of American automobile dealers and manufacturers to prevent reimportations, as had been currently rumored in the trade. The fact that they had discussed the matter diplomatically with the representative of the French Government shows that they were endeavoring to present the American business man's side of the problem to foreign governments, whose nationals had purchased Army supplies for speculative purposes.

It is understood that members of the Ways and Means Committee are in sympathy with the plan to protect the American market. As nothing has been adduced to show that the Commission which disposed of the surplus material made it obligatory upon the purchasers to sell in countries other than the United States, it is a matter which Congress alone has the power to control by specially designed legislation.

Tire Dealers Draw Protective Measures

Will Seek Handling of Bargain Stocks—Convention and Show in Cleveland

CLEVELAND, June 28—The first convention of the National Tire Dealers Association will be held in this city on Oct. 18, 19 and 20 at the Hotel Winton, which will be headquarters for the delegates.

A tire and tire accessories exhibition—the first of the kind to be held—will be conducted while the convention is in session.

These two decisions were reached at a meeting of the board of directors of the National Tire Dealers Association, which was held in this city June 21 and 22.

Resolutions placing the association on record against producers of tires or their representatives holding financial interest in retail stores and pledging the officers of the association to obtain data on offerings of standard tires at attractive prices and then forward same to members of the trade body, were adopted by unanimous vote.

Members of the board present included Thomas F. Whitehead, Chicago, president of the association; R. F. Valentine, Cleveland, vice-president; H. O. Stenzel, Milwaukee, treasurer, and Philip O. Deitsch, Cleveland, secretary.

The offer of the Cleveland branch of the national organization to finance the expense of the convention and to arrange an attractive program was responsible for the decision to meet here. The proximity of Akron, the center of the rubber tire industry, also was a controlling factor. There will be from 700 to 900 delegates in attendance, and Secretary Deitsch announced that a general invitation to all wholesale and retail tire dealers, regardless of whether they are affiliated with the organization, to attend the convention would be issued.

To Visit Akron Factories

Akron manufacturers will provide motor transportation for a trip by the delegates to the rubber city, and part of a day will be spent in the larger tire producing factories in that city so that all delegates may return home with some new talking points for their products and a better understanding of production methods.

To Valentine was delegated the responsibility of arranging the program for the convention and also for the tire and tire accessories show. He will announce committees shortly. Efforts will be made to obtain exhibits from every tire and tire accessory producer in America. While the features of the show have not been decided upon, already there is talk of inducing some producers to stage various phases of production. Educational features, such as lectures and demonstrations, to help the wholesale and retail tire dealer in his work are to have places on the program of the convention.

Under a resolution adopted, the secretary was directed to compile each month inventories of stocks in business establishments of dealers and distributers. The record so made up is to be given members of the association and manufacturers as a means of informing both on conditions in the trade.

Officers of the association have received many complaints from dealers relative to a certain producer of tires being financially interested in service stations scattered throughout the larger cities and along highways that are traveled to a large extent. It is charged that this concern gives free maintenance service to the detriment of the bona fide retail dealer who maintains a service department. Autoists who have been held up by flat tires in the country and have had a service truck come out from this concern's nearest branch and make free repairs or adjustments have complained when dealers charge for similar service.

Executives of the association also were instructed to watch keenly for opportunities to purchase standard tires at low prices. It frequently happens, according to information received at headquarters here, that producers of automobiles when forced to cut production of cars are caught with large stocks of tires. When their bankers ask them to liquidate their inventories, they proceed to dump tires on the market at reduced prices. The dealers want the first opportunity to purchase these tires.

Copies of the resolutions adopted will be mailed to car makers, tire producers and the national trade organizations of each.

Receiver Is Named for Republic Rubber

YOUNGSTOWN, June 27—G. H. Booth, vice-president, has been appointed receiver for the Republic Rubber Corp. by Judge D. C. Westenhaver of Cleveland. Suit was filed against the Republic Rubber Co. by Elizabeth Hines Gates of New York, a preferred stockholder, and against the Republic Rubber Corp., by Arthur L. Irish, a former Republic official, who claims to hold 90 per cent of the common stock.

The company claims to have purchased large quantities of cotton and rubber at high prices and that price declines were such that they could not manufacture and sell profitably. They have outstanding commitments on these goods amounting to $2,000,000. A. L. Irish alleges that the company owes $500,000 in past due notes. Bank loans are reported to aggregate about $2.000.000. Other loans will amount to several hundred thousand dollars.

Reports are to the effect that much of the company's losses are represented by new contracts made after much of the original loss had been largely cleared away by former president, E. F. Jones.

The manufacturing plants will be operated for a time at least, it was stated to-day. The receiver is working on a policy to be pursued in handling the property.

Akron Well on Way to Normal Business

Factory Schedules Placed Higher for July—Would Avoid 1920 Peak Conditions

AKRON, June 28—Present conditions in the industry do not assume the aspect of a boom and the tire industry is far from normal. But the marked improvement of the past four weeks both in car manufacturers' original equipment specifications and in the steadily increasing volume of dealers' sales affirms the opinion that the curve of tire production definitely and permanently is upward.

June 20 Goodyear called for 1200 tire builders. Two days later Goodyear called for 1500 more tire builders, and took on even additional men, absorbing approximately 3000 men during the week. Just what Goodyear's production will mount to has not been determined. Before re-employing the 3000 men, however, the company had climbed to a production ticket of 20,500 tires a day. That the Goodyear increase will approximate 50 per cent of present production is almost certain. This will carry the company back to a position far above normal and closely approaching peak production of a year ago last May.

Officials of the company claim that dealers' sales compare favorably with any normal week in the company's history and are larger than the corresponding weeks of last year. In addition car manufacturers have unexpectedly doubled and some have trebled tire specifications for July.

The Firestone factories, in order to handle increased dealers' orders and car makers' orders, have gone to two full 9-hour shifts daily and a 5½-day week. This will carry Firestone back to at least 20,000 tires a day. Goodrich continues at about 15,000 tires daily and has announced no contemplated production increase.

General Business Better

Business conditions in Akron already show the reflection of the improvement in the tire industry. The reinstatement of the 24-hour daily schedule has necessitated augmented street car service to East Akron. Business houses report that retail business shows the stimulation already. Financial conditions are tight and apparently immobile, but the general impression exists that Akron is well on the way to normal conditions.

The city, however, does not want a return to peak conditions. Akron does not want a floating population. It does not want thousands of transient laborers—the "suit case chaps," as they were called—increasing labor turnover, causing congestion in residential districts and swelling the city's crime record and night life. All manufacturers re-employing men are showing preference to Akron men now out of work.

Tire Demand Heavy in Chicago District

Price Reductions Influence Resumption in Buying—Farmer Sales Reported Better

CHICAGO, June 27—Direct reports from the large tire distributors in the Chicago territory, which in most cases covers three or four States (Indiana, Illinois, Wisconsin and Iowa), range through all the degrees of business activity from "good," which represents zero, to "three times the volume of business we were doing a year ago," which is the summer heat point without any shade. It is confusing to try to account for these widely ranging reports of business conditions and it is just as satisfying, perhaps, not to try to account for the statements and say that the tire business in this territory is unusually good and far beyond anything that the distributors thought they had a right to expect. The pick-up came very suddenly and at once grew into steady sales.

Price reductions in all the standard makes of tires have had the heaviest influence in stimulating sales. Cars that were running without "spares" are fast adding extra tires; old tires that were given long mileage during the long open winter are now being replaced.

Throughout the corn belt in the Middle West there is a disposition on the part of the farmers to buy. This tendency on the part of this enormous potential market is taking hold slowly, but is noticeable and growing steadily. This condition is particularly encouraging in the Northwest.

There are reports from spots in the rural sections where buying is at a standstill caused, it is said, by the fact that country banks have begun to realize on the farmers' notes they have been holding. With all conditions taken into consideration farmer trade is on the increase and by early fall it is thought this trade will have reached its climax.

AMAZON RUBBER OFFERS PLAN

AKRON, June 27—The Amazon Rubber Co. has asked its creditors to accept 75 per cent of their claims in full settlement. The proposal is for payment of 10 per cent in cash and 5 per cent each month thereafter until the amount is paid. If this plan is not accepted it is understood that the company will be forced into bankruptcy.

G. M. C. DECLARES DIVIDEND

NEW YORK, June 30—Directors of the General Motors Corp. at a meeting this afternoon declared the usual dividend of 25 cents a share on the common, $1.50 a share on the 6 per cent preferred and the 6 per cent debenture, and $1.75 a share on the 7 per cent debentures. The resignation of R. H. Collins as a vice-president and director was accepted, and Fred J. Fisher was elected a vice-president and director.

HORSES IN CITIES SHOW BIG DECREASE

WASHINGTON, June 28—The Bureau of the Census, Department of Commerce, announces that 56,539 horses were reported in the city of New York at the census of 1920, as compared with 128,224 reported at the census of 1910. There has been a similar marked decrease in the number of horses in all the principal cities in the United States so far as heard from. Chicago had 30,388 horses in 1920, as compared with 68,122 in 1910; Philadelphia, 19,472 in 1920 and 50,461 in 1910. In Baltimore the number of horses reported at the censuses of 1920 and 1910 was respectively 7378 and 15,346; in Boston, 10,093 and 23,007; in Pittsburgh, 6032 and 12,845; in Cincinnati, 5031 and 13,901; in Cleveland, 4924 and 16,839.

Barton Axle Company Goes Into Receivership

MILWAUKEE, June 27 — Henry J. Griessel, cashier of the State Bank of Barton, Wis., has been appointed receiver of the Barton Axle Co. of the same place, on the application of a number of local creditors. Within the last 18 months the corporation was organized and promoted, and built and equipped a plant to manufacture passenger car and motor truck axles. The complaint recites that the concern sold between $400,000 and $500,000 of capital stock supposedly to return 8 per cent, but that these shares have since proved to be worthless.

It was to have sold its product through the American Axle Co. of Chicago, at a large profit, but the American company never was actually organized, it is declared. When the Barton company set out to dispose of its own production, it was found that the axles were not salable, the complaint says. The County Court at Fond du Lac, Wis., which heard the complaint on a change of venue from Washington County, denied the request of the officials of the corporation for more time to straighten up accounts and general affairs, and a receiver was then appointed.

ANTIGO BUILDS NEW TRACTOR

ANTIGO, WIS., June 27—The Antigo Tractor Corp. expects to complete the first model of a new design of the Antigo Quad-Pull tractor on July 15, and have the first ten commercial machines ready for delivery by Aug. 1. Production is being carried on at outside points pending the construction and equipment of permanent works in Antigo during the fall and winter months. Parts are being made in Milwaukee, Fond du Lac and Oshkosh, and assembled at Fond du Lac, under the personal supervision of Herman Freudenberg, general superintendent.

Hydraulic Company Defers Merger Plan

Option on Detroit Pressed Steel to Lapse Unless Directors Reconsider

CLEVELAND, June 27—Upon recommendation of the directors, stockholders of the Hydraulic Steel Co. decided to take no action on the plan for a merger with the Detroit Pressed Steel Co. This automatically holds up the proposed increase in the stock of the corporation to enable it to purchase the stock of the Detroit company, according to R. D. Mock, vice-president of the Cleveland corporation. It is understood the option on the Detroit property will be allowed to lapse but there may be another meeting.

The letter which the Hydraulic Steel Co. submitted to its stockholders stated that an option to buy the Detroit plant had been obtained. There were two provisos attached to the exercise of the option on or before July 1, as follows: "The directors are not committed to the purchase of this property and will only do so on or before July 1 provided in their judgment (a) the purchase is a distinct advantage to this company in every respect, and, (b), they believe the financial condition of the Detroit company to be such as to sustain its own operation."

Under the option obtained the local company was to deliver three shares of common stock for four shares of the Detroit corporation. This would require the issuance of 54,000 shares of common stock. It further provided that payments for the Detroit plant's 50,000 shares of series A common (second preferred) of the par value of $1,250,000 may be made by the issuance of $850,000 par value of a second preferred stock of this company. The Detroit plant's net worth is $5,100,000 from which must be deducted $600,000 of bonds and $1,500,000 of preferred stock outstanding, leaving a net worth of $3,000,000. This equity the Hydraulic company would obtain by payment of $850,000 of its second preferred and 54,300 shares of common stock. Interest requirements of the Detroit plant's bonds and preferred stock amount to $141,000 per year. Earnings have been on an average of $505,000 for 5½ years.

The Detroit Pressed Steel Co., manufactures frames, brake drums, housings and wheels. The Hydraulic Steel Co. took over and operates the plants of the Hydraulic Pressed Steel Co., this city, the Canton Sheet Steel Co., Canton, Ohio, the Cleveland Welding Mfg. Co., and the Hydraulic Steel Craft Co., this city.

BRAZIL RUBBER EXPORTS DROP

WASHINGTON, June 27—April exports of Brazilian rubber amounted to 3,244,080 lb., 2,566,753 lb. of which were shipped to the United States, the remainder going to Europe. Consul George H. Bevan points out that this is a decrease of 6,292,258 lb.

Defiance Truck Gets Chinese Concession

Will Supply Trucks and Equipment Over Twenty Year Period —Arranges Financing

TOLEDO, June 25—Charles H. Kettering, president, and J. C. Ayres, general manager of the Defiance Motor Truck Co., at Defiance, near here, were in Toledo this week conferring with bankers regarding financing a large increase in the business of their company.

It was announceed earlier in the week that the truck company had secured 20-year concessions from the Chinese Government to ship trucks and automotive equipment into the far-eastern territory. All the shipments will be imported under the direct supervision of the Chinese Government.

Similar concessions have been granted to great American companies manufacturing textiles, locomotives, agricultural machinery and other products.

During the life of the concession it is believed that the Chinese Government will take a share in the profits of the business rather than any duty charge on the products imported.

The details of the financing scheme have not been announced yet. It is hinted, however, that the Chinese Government will float a bond issue of $100,000,000 in this country to carry out the program.

The Defiance Truck Co., however, is planning on sending thousands of trucks to China as its part of the plan.

Financiers in Detroit and Cleveland, as well as Toledo, will probably be appealed to for help in the project.

Peruvian Business Best in Car Parts

LIMA, PERU, May 31 (By Mail)—Business in automobiles in Lima is a little more lively on account of the approach of the 100th anniversary of Peruvian Independence (to be celebrated the latter half of next July) than it otherwise would be under existing conditions.

Existing conditions consist of a currency that has lost in exchange value from one-third to one-quarter of its purchasing power; and a public without money to buy on account of the fall in the price of cotton, wool, sugar and copper, the chief products and exports of the country.

Very few automobiles are being imported on account of the unfavorable exchange. In addition there is talk of a scientific revision of the tariff, which makes merchants doubly cautious about buying. Then there is expectation of price reduction of automobiles in the United States.

At the present time in Peru, the best market is for repair parts and repair materials. Instead of buying new automobiles and new tires, people are repairing the old ones.

Very few tractors are being sold. Not even Fordson is moving. This is due to the fact that cotton is not being planted this year, the farmers holding what they have and not producing more, in the hope of causing cotton to go up in price.

Mexico Wants Service; Used Cars Not Selling

CHICAGO, June 27—The Koehler Dean Truck Co., distributor for Federal trucks in Texas and Mexico, writing from its Tampico, Mexico branch, expresses the desire to correct the impression that there is a lively market for used cars in Mexico.

"Mexico is a very poor market for used cars," says the letter. "It is nearly impossible to sell any make of cars that are not well represented by a good stock of parts and a service station. Many dealers are bringing automobiles and trucks to Mexico and selling them at a great loss. Lack of service is the big question. Where parts stocks are kept cars and trucks sell readily. Mexican, people who are able to buy machines usually want something high class and brand new."

Exchange Helps Renault Undersell in Sweden

WASHINGTON, June 27—Dealers in American automobiles in western Sweden are much concerned over the activity of the French motor car industry in Sweden, according to a report from Consul Walter H. Sholes, Goteborg. The low value of the French franc has made it possible for the Renault company to place in the Swedish market a four-seated 22-horsepower car with self-starter, electric lights and other modern equipment at 8000 kroner. The cheapest American car of the same class cannot be sold for less than 12,000 kroner. Automobile dealers insist that the Renault product is not of the high pre-war standard.

Renewed activity on the part of German motor car manufacturers also is in evidence. The Benz concern is entering upon an advertising campaign, and it would seem that dealers in Benz cars are financially supported and given large credits by the Benz factory.

DELCO MAKES GAINS IN FRANCE

PARIS, June 12 (By Mail)—Delco lighting and starting equipment is now built completely in the factory of the Continsouza company at Levallois, near Paris, for the French and Continental Europe markets. The annual report of this company, which holds Delco licenses for the Continent of Europe, declares that despite the general trade depression prospects are bright for Delco ignition. Even in France, where the magneto appeared to have an unassailable position, battery ignition is making considerable headway and the Delco system is being used on several high grade cars.

Emerson Sentences Are Upheld by Court

Promoters Must Serve One to Seven Years for Fraudulent Stock Sale

NEW YORK, June 27—The United States Circuit Court of Appeals has affirmed the convictions in June, 1918, of Nicholas Field Wilson, Robert T. Matches, William Loomis and C. R. Berry & Co. for using the mails to defraud in connection with the sale of stock in the Emerson Motors Co. It was charged that $1,500,000 was realized by boosting to $7 a share stock that had been bought for 17c. a share. The company was shown to have a plant worth not more than $100,000.

Wilson, who was the promoter, was sentenced to seven years in prison, while Matches, who handled the stock in Boston, was sentenced to three years. Loomis was given one year and Berry & Co. was fined $13,000. Since their conviction the defendants have been at liberty on bail.

The original allegations of the stockholders who filed a petition for a receiver in bankruptcy were that the company was originated as a "stock jobbing scheme." At the time the petition was filed the liabilities were "far in excess of $500,000."

The promoters of the company claimed they intended to manufacture a car which would sell at retail for $395, and that they had orders for 60,000 cars. It was asserted in October, 1916, that a plant had been purchased at Kingston, N. Y., and that 500 cars would be built that year with 30,000 in 1917. Manufacture really was begun on a small scale, but no dealer contracts were made.

The car was designed by R. C. Hupp, who formerly was with the Hupmobile Co., but he retired as vice-president and general manager before the affairs of the company were taken to the court.

COURT RETURNS LIQUOR CAR

INDIANAPOLIS, June 27—Restoration of an automobile to Otto S. Wilson of Chicago was ordered by Judge Geiger in Federal court this week. It had been confiscated by revenue agents when James Schaller of Chicago was arrested charged with illegal transportation of liquor. Evidence placed before Judge Geiger was that the revenue agents had turned the car to their own private and official use. He gave a severe reprimand to the agents in ordering the car restored to Wilson, who proved his innocence of complicity. Wilson is suing the revenue agents for $700 damages to the car while in their possession.

STUTZ OFFICIAL DIES

INDIANAPOLIS, June 28—Announcement is made of the sudden death of Maynard Chase, 53 years old, employment manager of Stutz Motor Car Co.

NEW CAR PRICES

BRISCOE MAKES $200 CUT

JACKSON, MICH., June 27—A cut of $200 on all models, effective July 1, is announced by the Briscoe Motor Corp. Cars at the new prices will be equipped with windshield wings, front and rear bumpers, running board pads and nickel radiators, if desired. The new prices are: Touring car and roadster $1,085, coupé and sedan $1,685, panel type delivery $1,160, screen type delivery $1,085. Prices are f.o.b. Jackson.

NATIONAL MAKES BIG CUT

INDIANAPOLIS, June 27—Price reductions ranging from $760 to $960, effective July 2, are announced on its various models by the National Motor Car & Vehicle Corp. The schedule of new and old prices follows:

	Old Price	After July 1, '21
Seven-pass. Touring.	$3750	$2990
Four-pass. Phaeton..	3750	2990
Two-pass. Roadster.	3750	2990
Four-pass. Coupe....	4900	3990
Seven-pass. Sedan...	4950	3990

STEPHENS SALIENT SIX CUT

FREEPORT, ILL., June 27—Price reductions running as high as $600, effective July 1, are announced by the Moline Plow Co. on all models of the Stephens Salient Six. The schedule follows:

	Old Price	New Price
92 Roadster..............	$2400	$1900
B-92 Roadster (Sport)....	2600	2000
94-B-94 Four Passenger Touring	2400	1985
94-A Four Passenger Touring (Sport)........	2600	2085
96 Six Passenger Touring	2400	2065
93 Four Passenger Sedan	3400	3100
95 Seven Passenger Sedan	3400	3100

LIBERTY PRICES REDUCED

DETROIT, June 28—The Liberty Motor Car Co. announces price cuts on all models effective July 1. The touring car and roadster are reduced from $1,795 to $1,595; the sport model from $1,985 to $1,675; the coupé from $2,825 to $2,400; and the sedan from $2,850 to $2,495.

STUTZ PRICES DOWN $650

INDIANAPOLIS, June 27—A reduction of $650 on all models is announced by the Stutz Motor Car Co., effective immediately. The roadster and "bearcat" models are cut from $3,900 to $3,250 and the four and six passenger open types from $4,000 to $3,350.

BARLEY MOTORS CUTS PRICE

KALAMAZOO, MICH., June 29—Cuts ranging from $100 to $650 effective July 1, were announced to-day by the Barley Motor Car Co. on its various models. The reductions follow: Four passenger touring from $3,250 to $2,985, roadster and four passenger sport from $3,375 to $3,150, seven passenger touring from $3,400 to $3,250, four passenger coupé from $4,250 to $3,985, five passenger sedan from $4,250 to $4,100; five passenger limousine from $4,500 to $4,000, five passenger landaulet from $4,650 to $4,000.

COLE CUTS $455 to $700

INDIANAPOLIS, June 29—Price reductions ranging from $455 to $700 on its different models were announced today by the Cole Motor Car Co. The new prices of the various models were not disclosed.

HATFIELD CAR REDUCED

NEW YORK, June 27—Cortland Cart & Carriage Co., Sidney, N. Y., manufacturer of the Hatfield car, has reduced prices on its 4-pass. model from $1,695 to $1,495, and on its sedan from $2,595 to $2,395.

HUBER CUTS TRACTOR PRICE

MARION, OHIO, June 27—The Huber Mfg. Co. has made a reduction of $200 in the price of its light four tractor. This takes the price back to the pre-war level.

MILLER CUTS TRUCK TIRES

AKRON, June 27—New prices on heavy duty pneumatic tires are announced by the Miller Rubber Co. The new schedule, as compared with the old, follows:

Size	Old Price	New Price
36 x 6	$119.35	$91.85
38 x 7	168.85	127.35
40 x 8	217.50	164.00
42 x 9	272.25	262.50
44 x 10	380.75	367.00

FORD CUTS PARTS PRICES

DETROIT, June 28—The Ford Motor Co. announces price reductions on parts ranging from 12½ to 50 per cent. The reductions cover more than 400 parts and in dollars and cents range from 1 cent on nuts and bolts to $12 on transmission assemblies.

Small Buying Continues in General Motors Stock

NEW YORK, June 29—One out of every five General Motors common stockholders is a woman. On April 15, 1921, there were 8110 women common shareholders compared with 3459 on Oct. 5, 1920, an increase of 4651. Women owned 1,467,368 shares of common April 15, an average holding of 180 shares each, compared with 1,201,334 shares Oct. 5, 1920, an average of 347 shares; an increase of 266,834 shares in the aggregate, but a decrease of 167 shares in the average.

On April 15, the date of record for stockholders who received May dividends, there were 37,787 individual common stockholders, compared with 16,681 on Oct. 5, 1920, the date of record for November, 1920 dividends. The changes during those six months are significant.

METAL MARKETS

STEEL consumers have grown unduly accustomed to the "official" method of price changes. This is a legacy of the War, when the War Industries Board, "with the approval of the President," would issue proclamations covering maximum prices, and these were considered first page stuff by the newspapers. Popular interest in the leading steel producing interests, because it is the largest industrial corporation of the land, continues to make price announcements by the United States Steel Corporation "must, first page." Important changes in the price of steel products, however, are coming to pass these days without being deemed worthy of scareheads. This is especially true of the kinds of steel in which the automotive industries are vitally interested. Cold-rolled strip steel is obtainable at fully $10 a ton less than a month ago. A similarly sharp price decline has taken place in fine-finished sheets. All of these downward price changes, however, fail to arouse any enthusiasm on the part of the buyer, who holds that they result from apathy on the part of the leading steel producers, who are permitting the market to drift, when, in the consumer's opinion, they should set their house in order as speedily as possible and announce the lowest possible price at which they can sell steel and make both ends meet. In spite of the seemingly lackadaisical attitude of steel producers, a change is coming over the situation, however, and, with production down to a quarter to a third of normal, the visible supply of steel is being constantly diminished. The major market in the last few weeks has been the resale market. Manufacturers with much steel and few orders on hand have been disposing of as much of their surplus as they possibly could to other manufacturers with a more immediate outlet for it. Jobbers have in some instances reduced their prices to a point where they could compete successfully with production steel. Daylight is beginning to dawn more and more. For all that, the belief is general that before long the leading interest will see fit to announce a reduction in prices. This impression is strengthened by the sharp criticism which one of the independent producers recently applied to the chief interest's price policy. The new iron ore price, which is $1 a ton below the 1920 level, is merely a trial kite. It looks as though 1921 ore demand would be negligible. The new ore price was established on the basis of a sale to Canada. There have been no domestic transactions at the new figure, nor are there any in sight. Theoretically speaking, $1 cut in the price of ore should imply a $2 per ton reduction in production cost of pig iron and steel.

Pig Iron.—Malleable is offered at $23, valley, and foundry $1 less. Even these low prices can be frequently shaded.

Steel.—Automotive parts makers are placing occasional orders for cold-drawn bars. Youngstown reports 5.20c. for fine finished sheets with 15 per cent seconds for 22 gage.

Aluminum.—The market continues utterly neglected, although some automotive interests are endeavoring to obtain a line on contract prices for 1921-1922 delivery.

Lead.—Spanish lead continues to come in. In the "outside" market metal as low as 4.05c., East St. Louis basis, is offered.

Zinc.—In the absence of consuming demand, the market is continually sagging with the nominal price at around 4.25c., East St. Louis.

FINANCIAL NOTES

Standard Parts Co. business totaled $600,000 in March, $1,000,000 each in April and May, and will aggregate $600,000 in June, according to a statement issued by Receiver Scott. All the receiver's debts have been paid excepting current accounts, and the company has $1,000,000 in the bank.

Miller Rubber Co., in a comparative balance sheet as of Dec. 31, shows total assets of $23,271,274, a gain of about $5,000,000 over 1919. The assets include cash of $2,012,388; accounts and notes receivable, $2,755,327, and an inventory of $9,321,803.

Chandler Motor Car Co. is in strong financial position, declares President F. C. Chandler, decrying rumors that the company would cut its October dividend. "Directors will not discuss the October dividend in June," he said.

Cincinnati Finance Co. moved last week into its permanent offices in the Dixie Terminal Building, Cincinnati. The company specializes in discounting automobile and truck installment payment notes from dealers.

Detroit Motorbus Co. has declared a dividend of 1½ per cent, payable July 15. This will be the first dividend since the company was organized. It now has 48 buses operating and 20 more soon to start.

Jackman Motors Co., Joliet, Ill., has been cited in a petition in bankruptcy filed by creditors. Liabilities are placed at $70,000 and assets at $60,000.

Kelsey Wheel Co. has declared the regular quarterly dividend of 1¾ per cent on the preferred stock, payable August 1.

Republic Motor Truck Co. directors have voted to pass the 1¾ per cent quarterly preferred dividend due July 1.

Motor Wheel Corp. paid a cash dividend on common stock of 2 per cent on June 20.

HOLTON TO CHANGE HANDS

INDIANAPOLIS, June 27 — Contract for the transfer of the Holton Tractor Co. of this city to the Kokomo company which will take over the tractor company's business will be effected as soon as Elwood Haynes of the Haynes Automobile Co. returns from New York. Negotiations for the transfer are being carried forward with the receiver here. The transaction will involve approximately $350,000. The Holton tractor company will probably be moved to Kokomo and it is understood that the strong features of a tractor manufactured at Elwood will be combined with the Holton invention. Others interested in the new company besides Haynes are A. G. Seiberling, George J. Marott of Indianapolis, Simeon McQuiston of Greentown and others.

MONARCH TRACTOR PLANT SOLD

WATERTOWN, WIS., June 27—E. D. Caldwell of New York was the highest bidder for the assets of the Monarch Tractor Co. of Watertown, Wis., at the public auction conducted at the plant by the trustee in bankruptcy, William B. Roys of Madison, Wis. The price of $44,000 was accepted subject to approval by the bankruptcy court. The Monarch company, together with its parent corporation, General Tractors, Inc., Paulsboro, N. J., recently was made defendant in bankruptcy proceedings and the entire properties were ordered sold. Caldwell is a large stockholder in the General Tractors company and a principal creditor as well. The Monarch plant at Watertown is carried for 1921 on the assessment roll of the city of Watertown at a valuation of $168,000. Inventory appraisal in bankruptcy proceedings gave the value as $40,000.

INDUSTRIAL NOTES

American Grinder Mfg. Co., manufacturer of wrench sets, portable tool grinders and similar specialties, is moving into a new factory, comprising the entire second floor of the Milwaukee Terminal Building, affording about 50,000 sq. ft. It will be ready to resume operations July 1 or 5 in the new quarters.

Link-Belt Co. of Chicago, headed by Charles Piez, has acquired all the capital stock of the H. W. Caldwell & Son Co. Frank C. Caldwell has been elected a director by the Link-Belt Co. and operation of the Caldwell plant as a separate unit will be continued.

John Broenen Co., Milwaukee, has let contracts for the erection of a two-story brick and concrete addition, 50 x 75 ft. It is a manufacturer of passenger car and motor truck bodies.

Hebb Motors Works at Havelock, Neb., were sold at auction to W. H. Ferguson of Lincoln for $110,000, subject to the approval of the court. The plant cost $3,000,000.

Paige-Detroit Motor Car Co. has declared the regular quarterly dividend on preferred stock of 1¾ per cent, payable July 1 to stock of record June 15.

Kant-Score Piston Co. has acquired the Cincinnati plant of the D. T. Williams Valve Co.

Cadillac Tool Co. has increased its capital stock from $40,000 to $200,000.

JORGENSON RESUMES JULY 1

WAUPACA, WIS., June 27—The Jorgenson Mfg. Co., a large manufacturer of priming devices and brass castings for the automotive industries, will resume production on a normal scale shortly after July 1. The machine shops were closed late in May after a steady day and night run for nearly a year's time to enable the company to overhaul the plant, rearrange equipment for greater efficiency and to do some retooling. The foundry was kept in continuous operation to insure a casting supply when the machine departments resume. The interruption was a seasonal one, as demand for priming devices usually falls off after the cold weather is over. Manufacturers and jobbers are now placing orders for fall and winter deliveries and it is expected to maintain steady production for a year.

CAROLINA WOODWORK HIGH

COLUMBIA, S. C., June 25 — South Carolina now has more miles of Federal aid highways completed or under construction than any of the five Southern States, Tennessee, South Carolina, Georgia, Florida or Alabama, with the exception of Georgia.

BANK CREDITS

Written exclusively for AUTOMOBILE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, June 30—The improvement in the reserve position of the New York Federal Reserve Bank attracted much interest last week. The ratio of gold reserves to Federal Reserve notes in circulation after setting aside 35 per cent against deposit liabilities, increased from 90.8 per cent to 103 per cent. The ratio of total reserves to deposit and Federal Reserve note liabilities combined, increased from 60.6 per cent to 68.9 per cent. This improvement was largely a result of a $132,682,000 decline in total deposits and a $25,106,000 increase in gold reserves. Federal Reserve notes in circulation in this district also declined $13,541,000. This improvement furnishes substantial background for the further reduction from 6½ per cent to 6 per cent of the bank's discount rate on commercial paper. Similar action was taken by the Dallas Federal Reserve Bank, and, as a result, all Federal Reserve Banks of the system now have a 6 per cent rate on commercial paper, with the exception of the Minneapolis and Chicago banks, which still maintain a 6½ per cent rate.

The action of the New York bank was followed by similar action on the part of the Bank of England, which reduced its discount rate from 6½ per cent to 6 per cent on June 23, after having reduced it a short time ago from 7 per cent to 6½ per cent. The effect of the reduction by the Bank of England on trade has apparently been minimized somewhat by the continuance of the coal strike. This strike was settled on June 28 and should allow England to proceed uninterruptedly towards a normal recovery of its economic life. There appears to be ample evidence that the banking situation is laying the foundation for easier credit in the future.

The local call money market gave evidence of considerable ease last week when the renewal rate reached 5 per cent on the Stock Exchange for the first time since October 27, 1919. The range for the week was 5 per cent to 5½ per cent as against 5½ per cent to 6 per cent the previous week, although 5 per cent was the maximum rate on all days except Monday. There were said to be large supplies of unloadable funds at the end of each day for which no market was found, and on the "outside" market considerable business was done at 4 per cent. Time money was unchanged at 6½ per cent for 60 and 90 days' and 4 months paper, and 6 per cent to 6½ per cent for 5 to 6 months' paper. There was little activity and most of the trades were restricted to renewals for short periods. The commercial paper market was dull, with rates unchanged at 6½ per cent to 6¾ per cent for 60-90 days' endorsed bills and 6 months' names of prime character.

The market continued the decline characteristic of recent weeks.

MEN OF THE INDUSTRY

Earl B. Spencer has been appointed production manager of the Leach Biltwell Motor Car Co., Los Angeles. He was formerly a plant engineer at the Pierce-Arrow factory and later assistant general superintendent. During the war he was in charge of the organization manufacturing Hispano-Suiza aircraft.

D. F. Hulgrave has been appointed manager of purchases for the Cadillac Motor Car Co., succeeding J. H. Main, who has been named director of the purchase section of the General Motors advisory board in Detroit. Hulgrave has been with the company for thirteen years, the latter three being assistant to Main.

John A. Cleary has resigned as advertising manager of the Cadillac Motor Car Co. to become advertising manager for the new Collins car. Cleary has been with Cadillac for a number of years, serving as sales promotion manager with the Philadelphia distributor before making the factory connection.

M. J. Flannery, formerly of the General Motors Export Corp. and the John N. Willys Export Corp., has been named assistant export manager for the Haynes Automobile Co. His office will be at 1715 Broadway, from which all foreign sales of the Haynes, except in Mexico, will be handled.

L. M. Rankin, vice-president and general manager of the Duesenberg Automobile & Motors Co., has appointed Harry W. Anderson as general sales manager of the company, with headquarters at the new Duesenberg plant in this city. He will begin upon his duties immediately.

R. S. Schaap, sales manager of the Schaap Co., Brooklyn, has left on a western trip, on which he will inspect several locations as the site of the company's proposed western plant. He will also appoint a number of western distributors for his company's products.

Thomas Mair, former comptroller for the Chevrolet company, has been transferred to the Oakland Motor Car Co., where he will succeed E. H. Tinsman, who has been transferred to the general comptroller's office of the General Motors Corp. at Detroit.

Frederick C. Horner, for several years transportation engineer of the Packard Motor Car Co., New York, is leaving the company to spend two years in Europe studying transportation practice in England, France, Belgium and Germany.

F. R. Robinson, secretary of the Packard Motor Car Co., has assumed also the duties of treasurer. He has been in the Packard organization for the past twelve years, holding successively the positions of auditor, comptroller and secretary.

W. B. Kelly, for 13 years works manager of the Oakland Motor Car Co., has resigned. He states that he has no definite plans for the future, but it is presumed he will join the Durant forces.

H. R. Hyman has resigned as advertising manager of the Cole Motor Car Co., Indianapolis. He will rest for several months before announcing plans for the future.

C. B. Rice, New York, who has been manager of exports for the Hamilton Motors Co., will also assume control of domestic sales of the company.

J. K. Harness has resigned as patent counsel for the Ford Motor Co. to resume private practice.

J. G. White has been appointed district sales manager at Detroit of the Sharon Pressed Steel Co., Sharon, Pa.

OTTAWA CAR BUILDER DIES

W. W. Wylie died here June 24 at the age of 61. He was for twenty years manager of the Ottawa Car Co. and manufactured the first street cars to run in the city as well as the first snow plows for use in clearing street-car tracks in winter. He built and ran the first motor car to speed through the city in 1894, the seat being pitched high on four very heavy solid wheels and the electric motor fitted to the box under the seat. The trial spin was the cause of much interest and amusement to pedestrians who watched the rather uncertain movements with some misgiving. In 1912, Mr. Wylie resigned the managership of the company which was later incorporated and now operates one of the best motor showrooms in the city as well as a large repair department.

INVENTOR SUES VAN BRIGGLE

INDIANAPOLIS, June 27—Suit has been filed in Circuit Court by George G. F. Boswell, inventor, asking for an injunction restraining Lilburn Howard VanBriggle of the VanBriggle Motor Device Co. and promoter of the interests of several manufacturing concerns of this city from making or selling shock absorbers or parts of shock absorbers.

Boswell charges in his complaint that he entered into an agreement with VanBriggle, April 12, 1918, for handling and making shock absorbers, on which he held patent rights. Full patent letters on the shock absorber were received in December, 1919, but since that time no shock absorbers have been manufactured by VanBriggle, and notice was served on him April 21, 1921, of the cancellation of the contract, according to Boswell. In the complaint, Boswell charges that VanBriggle is making the shock absorbers and he has, therefore, asked that such a restraining order be issued.

NEW PATENT BILL HELD UP

WASHINGTON, June 27 — Efforts to amend the patent law providing that foreigners shall within two years manufacture the article in the United States, or, in the discretion of the department, some other person may be granted a license to manufacture it, failed to pass the Senate to-day on objection of Senator Brandegee of Connecticut. His objection was based upon the protest of Frederick P. Fish, of Boston, a patent lawyer well known in the automotive trade, who declared that the amendment was dangerous because it established a precedent and opened up the question of a time limit upon when the granting of a patent must result in putting the article or commodity so patented upon the market. The Senate committee on patents has asked the views of the Commissioner of Patents and the Secretary of War before considering the bill in open session.

Truck Auction Bids Appear Fictitious

(*Continued from page 1453*)

for $2,500; 3½-ton Packards sold for $2,000; chain-driven 3-ton Whites for $1,900; and 4-ton Rikers for $1,800.

In the opinion of prospective buyers on the floor, to-day's prices did not indicate anywhere near the true valuation of the trucks. A representative of one of the large truck manufacturers stated that his company was given the opportunity to purchase a certain make of truck in lots for $350 each.

Each truck was sold with a guarantee against defective parts within 30 days of the purchase. Arrangements were made by the auctioneers for the sale of the trucks under the part payment plan, representatives of finance companies being on the floor.

OLDSMOBILE REVISES PRICES

NEW YORK, June 30—Price reduction on several models of the Oldsmobile, ranging from $45 to $575, and increases on two models, will be effective July 2. There will be reductions all along the line on the Model 43-A, the 4-cylinder car, and on the Model 46, big 8-cylinder. On the light 8, Model 47, the coupe is reduced, while the sedan is increased $30 because it could not be built at a profit at the old price. The light 8 touring car, a four-passenger job, is increased $30 because of the change from fabric to cord tires.

Prices of the 6-cylinder model will be unchanged.

PREMIER PRICES SLASHED

INDIANAPOLIS, June 30—The Premier Motor Car Corp., beginning July 1, will cut the prices of its cars from $710 to $910. The reductions are: Four-pass. touring from $4,600 to $3,690; 4-pass. sedan from $6,000 to $5,090; 7-pass. touring from $4,600 to $3,890; 7-pass. sedan from $6,100 to $5,190, and coupé from $5,600 to $4,690. There will be practically no changes in design and construction of the 1921 model.

WESTCOTT PAYS DIVIDEND

SPRINGFIELD, OHIO, June 29—Directors of the Westcott Motor Car Co. and the H. G. Root Co., automobile supplies, have authorized the payment of the regular quarterly dividend of 2 per cent on the preferred stock payable June 30.

BURY SHIFTS JOBS

DETROIT, June 29—G. R. Bury, general sales manager of the Packard Motor Car Co., has resigned on account of ill health and will go to Los Angeles to become associated with the Packard distributor in that territory. His successor has not been named.

Calendar

SHOWS

Sept. 5-10—Indianapolis, Automobile and Accessory Show in conjunction with Indiana State Fair, conducted by Indianapolis Automobile Trade Association, John B. Orman, Mgr.

Sept. 28 - Oct. 8 — New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January — Chicago, Automobile Salon, Hotel Drake.

FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment. La Pabellon de las Rosas. Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery. Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

CONVENTIONS

July 4-9 — Mackinac Island, Mich., Summer Meeting Automotive Equipment Association.

Oct. 12-14, 1921 — Chicago, Twenty-eighth Annual Convention National Implement & Vehicle A'ssn.

Nov. 22—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

RACES

July 25—Grand Prix, Le Mans.

Labor Day—Uniontown, Pa., Autumn Classic.

Mixed Fuel Exempted from French Gas Tax

PARIS, June 12 (By Mail)—Gasoline mixed with alcohol or with benzol is now exempt from the French State tax of 20 centimes per litre. The decree declares that the mixture can be either 50 per cent alcohol and 50 per cent gasoline, or a mixture in equal proportions of gasoline, alcohol and benzol.

The French State gasoline tax initiated last year, always has been very unpopular and has brought forth innumerable protests from both manufacturers and automobile users, without, however, moving the authorities. All the big trucking interests are in favor of the use of a fuel composed of gasoline, alcohol and benzol, which experiments have shown can be satisfactorily employed in present engines. To get this on the market, however, it is essential that the price of the mixture should be lower than straight gasoline, and this has not been possible up to the present owing to the instability of alcohol prices and variations in the supply. The abolition of the State tax is a certain step in the direction of the adoption of this mixture.

As a further effort, a competition is now announced, with $50,000 in cash prizes for devices which will encourage the use of alcohol in internal combustion engines. Agricultural experts are also at work endeavoring to convince farmers of the advantage of occasionally raising beet crops in order to improve their land for wheat crops. The beets will be used for distilling alcohol, and at the same time the yield in wheat will be increased, it is declared, from 20 to 30 per cent.

Plane Service Connects Paris with Le Havre

PARIS, June 12 (By Mail)—Regular airplane service between Paris and Le Havre, a distance of 130 miles will be established this week in order to carry passengers to and from Atlantic liners using this port. This airplane service is being organized by the Compagnie des Messageries Aeriennes in conjunction with the French Line steamship company, whose liners sail from this port.

A protest has been made by the French aerial navigation companies against the Government plan of forming elaborate aerial stations, with sheds, equipment, and an expensive staff, on the main aerial routes. The operating companies maintain that all that is required is a chain of suitable landing grounds at intervals of not less than 30 miles along the entire route between Paris and London and Paris and Brussels. On the Belgian portion of the Paris-Brussels air line this view has been accepted, and the Air Ministry is now preparing emergency landing grounds at 30 mile intervals.

Lack of Roads Hurts Car Sales in Formosa

WASHINGTON, June 28 — American manufacturers of automobiles, trucks and tractors having the best success in Formosa are those whose agents have branches there equipped to give demonstrations, according to a report by Consul Henry B. Hitchcock, Taihoku, Taiwan, Japan, relating to conditions affecting the sale of these vehicles in Formosa. It also is urged that the value of judicious advertising should not be overlooked.

He states that the market for passenger vehicles and trucks in Formosa is as yet but a small one. Roads in the rural districts are not wide enough or sufficiently well maintained to be used for motor vehicles. In the large cities, however, the streets are generally wide and well kept up. The use of passenger automobiles and trucks is consequently confined to the large cities, of which there are but three with a combined population of 270,478. While the financial depression has not been felt so much in Formosa as in Japan, it will nevertheless have an effect on the sales of passenger automobiles and trucks for some time.

NASH MAKES CUT IN SALARIES

KENOSHA, WIS., June 27—At a mass meeting of all straight-time workers in the plant and offices of the Nash Motors Co., Kenosha, Wis., it was announced that the entire salaried force would receive a slight reduction effective July 1.

South Africa to Make Gasoline Substitute

WASHINGTON, June 27 — Penrol, South Africa, Ltd., is marketing 85,000 shares of stock to secure initial working capital for the production and sale of "Penrol," a gasoline substitute, according to a report made to the Bureau of Foreign and Domestic Commerce. This new fuel will be made principally from alcohol which will be produced from locally grown maize or mealies (corn). It has been patented in the Union of South Africa and its name registered. The advantages claimed are as follows:

It can be manufactured in South Africa solely from ingredients and constituents produced locally; the selling price will be considerably below that of gasoline; in power and driving force it is practically equal to gasoline; it has no smell and does not carbonize; it is non-corrosive, smokeless and stainless. Penrol has been subjected to trials and experiments for a considerable period in motor cars, motor cycles, motor trucks, and airplanes over a distance of 10,000 miles, with excellent results, according to reports from experts and leading firms.

The total gasoline consumption of the Union of South Africa is estimated at 12,000,000 gal. annually by the company, but the total for the past year was only about 11,000,000 gal. By-products of cattle feeds and other lines are also contemplated.

FORD LOWERS HOUSE PRICES

DETROIT, June 28—In line with his determination to bring about price readjustments in accordance with business conditions, Henry Ford has announced substantial price cuts on Ford homes in Dearborn. These suburban residences now are selling at low figures and at terms which are making them attractive to investors who naturally are numbered chiefly among the Ford employees. Ranging between $6,900 and $8,500, according to type, prices are considerably below market value for property in this section. The terms being allowed make the offers unusually attractive, Ford permitting down payments as low as 10 per cent and monthly installments varying from $38 to $85.
